7. In a rotary motor, the combination of an exhaust-jacket, a wheel having return or exhaust blades, a motor-wheel surrounded by a casing, an explosion-chamber provided with an outlet or nozzle arranged to deliver the products of explosion to the motor-blades, and a pipe supplied with suitable cooling fluid arranged to project such fluid into the said outlet or nozzle as over the heated gases before their impact on the motor-blades.

700,377. GAS IMPACT-ENGINE. LISA WILSON, Brooklyn, N. Y. Filed Aug. 14, 1901. Serial No. 71,598. (No model.)

Claim.—1. A gas impact-wheel having a series of numerous closed channels upon its periphery disposed in the general direction of its desired rotation, the channels having inlets arranged upon the periphery and outlets upon the edge of the wheel, and a nozzle arranged upon said periphery to project gas into the inlets, substantially as herein set forth.

2. A gas impact-wheel having two series of numerous closed channels disposed at opposite divergent inclinations upon its periphery in the general direction of its desired rotation, with inlets arranged upon the periphery, and outlets upon the edges of the wheel, and one or more nozzles arranged around said periphery to project gas into the inlets, substantially as herein set forth.

3. A gas impact-wheel having two series of numerous closed channels disposed at opposite divergent inclinations upon its periphery in the general direction of its desired rotation, with inlets arranged upon the periphery, and outlets upon the edges of the wheel, a stationary guard over the inlets and one or more nozzles inserted through the guard around the said periphery to project gas into the inlets.

4. A gas impact-wheel having two series of numerous closed channels disposed at opposite divergent inclinations upon its periphery in the general direction of its desired rotation, with inlets arranged upon the periphery, and outlets upon the edges of the wheel, a stationary guard over the inlets and one or more nozzles inserted through the guard around the said periphery to project gas into the inlets.

5. A gas impact-wheel having two series of numerous closed channels disposed at opposite divergent inclinations upon its periphery in the general direction of its desired rotation, with inlets arranged upon the same peripheral line, and outlets upon the edges of the wheel, one or more nozzles arranged around said peripheral line to project gas into the inlets, and the channels being formed in sectional parts extended from one edge of the wheel to the other, said parts being adapted to fit together upon the surface of the wheel.

6. A gas impact-wheel having two series of numerous closed channels disposed at opposite divergent inclinations upon its periphery in the general direction of its desired rotation, with inlets arranged upon the same peripheral line, and outlets upon the edges of the wheel, one or more nozzles arranged around said peripheral line to project gas into the inlets, and the channels being formed in sectional parts extended from one edge of the wheel to the other and curved at their outlets to reflect the movement of the escaping gas.

7. A gas impact-wheel having two series of numerous closed channels disposed at opposite divergent inclinations upon its periphery in the general direction of its desired rotation, with inlets arranged upon the same peripheral line, and outlets upon the edges of the wheel, one or more nozzles arranged around said peripheral line to project gas into the inlets, and the channels being arranged in pairs with a common inlet at their junction, and the partition c in each inlet to divide the gas projected therefrom.

8. A gas impact-wheel having two series of numerous closed channels disposed at opposite divergent inclinations upon its periphery in the general direction of its desired rotation, with inlets arranged upon the same peripheral line, and outlets upon the edges of the wheel, one or more nozzles arranged around said peripheral line to project gas into the inlets, the channels being arranged in pairs with a common inlet at their junction, the partition c in each inlet being formed with the shoulder d at each side, and the divergent portion of each channel extending from each shoulder forwardly in the direction of the desired rotation.

9. A gas impact-wheel having two series of numerous closed channels disposed at opposite divergent inclinations upon its periphery in the general direction of its desired rotation, with inlets arranged upon the same peripheral line, and outlets upon the edges of the wheel, one or more nozzles arranged around said peripheral line to project gas into the inlets, the channels being arranged in pairs with a common inlet at their junction, the partition c in each inlet being formed with the shoulder d at each side, the divergent portion of each channel extending from each shoulder forwardly in the direction of the desired rotation, and the outlet of the channels upon the edges of the wheel being reflexed, substantially as and for the purposes set forth.

10. A gas impact-wheel formed with the drum-sections A and A' having the closed channels a and a' formed thereon as set forth, the channels a being disposed at opposite divergent inclinations to the center line of the drum A and curved backwardly at their outer ends, and the channels a' being inclined and extending from one edge across and upon the periphery of the drum A', the rings I contained between the adjacent ends of the channels a and a' with the intermediate curved deflection f therein forming closed reflexed passages adapted to reverse the movement of the gases as set forth, a guard surrounding the inlets of the channels a situated around the periphery upon the center line of the drum A, and one or more nozzles extended through each guard to supply the channels with the gases.

11. A gas impact-wheel having two series of numerous closed channels disposed at opposite divergent inclinations upon its periphery in the general direction of its desired rotation, with inlets arranged upon the same peripheral line, and continuous annular guard-chucks f projected at the exterior sides of the inlets, with a stationary guard g attached to the casing and fitted between the chucks f, and one or more nozzles extended through each stationary guard to supply the inlets with the gases.

700,378. REVERSELY CURVED PROPELLER. LISA WILSON, Brooklyn, N. Y. Filed Sept. 20, 1901. Serial No. 75,871. (No model.)

Claim.—1. A screw-propeller having a hub with some flanges, the hub attached to the propeller-shaft, propeller-blades having each a base provided with a flange having teeth and fitted to its respective cast, a collar secured upon the cast over each of said flanges, said flanges extended through the collar parallel with the shaft and engaged with the teeth on their respective several flanges, the propeller-shaft being hollow, and a screw fitted within the end of the shaft and having a bolt attached to

the racks, and a shifting-rod attached to and extended from the sleeve through the interior of the shaft to shift the sleeve as required.

2. A screw-propeller having a hub with seats thereon, the hub attached to the propeller-shaft, propeller-blades having each a base provided with a flange having teeth and fitted to its respective seat, a collar secured upon the seat over each of such flanges, appliances to limit the arc through which the blades can turn on the seat, and racks extended through the collars parallel with the shaft and engaged with the teeth upon their respective several flanges, and means for moving the racks to turn the respective blades upon their seats simultaneously.

3. A screw-propeller having a hub with seats thereon, the hub attached to the propeller-shaft, propeller-blades having each a base provided with teeth and fitted to its respective seat, and their shanks flared from the flanges toward the blades, a collar secured upon each seat and fitted to embrace the flange and flaring portion of the shank, and racks extended through the collars parallel with the shaft and engaged with the teeth on their respective several flanges, with means for moving the racks to turn the respective blades on their seats simultaneously.

4. A screw-propeller having a hub with seats thereon, the hub attached to the propeller-shaft, propeller-blades having each a base provided with a flange having teeth and fitted to its respective seat, a collar secured upon the seat over each of such flanges and fitted to admit a rack to engage with the teeth upon its respective flange, racks extended through the collars parallel with the shaft and each rack engaged with the teeth upon its respective flange, a sleeve attached to the racks to shift them simultaneously parallel with the shaft, and stops applied respectively to the blades and to the collar to contact at the extremes of the desired arc turning movement to limit it and to support the blades at such extreme positions independently of the rack.

5. A screw-propeller having a hub with seats thereon, the hub attached to the propeller-shaft, propeller-blades having each a base provided with teeth and fitted to each seat, and their shanks flared from the flanges toward the blades, a collar secured upon each seat and fitted to embrace the flange and flaring portion of the shank, and racks extended through the collars parallel with the shaft and engaged with the teeth on the respective several flanges, with means for moving the racks to turn their respective blades on their seats, a segmental recess in the collar adjacent to the shank and a stud upon the shank to contact with the ends of such recess and limit the arc turning movement of the blades, substantially as herein set forth.

6. A screw-propeller having a hub with seats thereon, the hub attached to the propeller-shaft, propeller-blades having each a base provided with a flange having teeth and fitted to its respective seat, a collar secured upon the seat over each of such flanges, appliances to limit the arc through which the blades can turn on their seat, and racks extended through the collars parallel with the shaft and engaged with the teeth upon their respective several flanges, and means for moving the racks to turn the respective blades upon their seats simultaneously, each collar being divided and each segment thereof fitted to the flange and shank of its respective blades, the contiguous parts of the divided collar being provided with flanges and bolts for clamping them together and to the hub.

7. A screw-propeller having a hub with seats thereon, the hub attached to the propeller-shaft, propeller-blades having each a base provided with teeth and fitted to each seat, and their shanks flared from the flanges toward the blades, a collar secured upon each seat and fitted to embrace the flange and flaring portion of the shank, and racks extended through the collars parallel with the shaft and engaged with the teeth on their respective several flanges, and means for moving the racks to turn the respective blades on their seats simultaneously each collar being divided and each segment thereof fitted to the flange and shank of its respective blades, the parts of the collars between and bearing on adjacent blades being formed in one piece and fitted to the hub, the respective flanges and shanks, and the contiguous parts of the divided collars being provided with flanges and bolts for clamping them together and to the hub, whereby all the segments are united to one another and to the hub, substantially as and for the purposes set forth.

8. The combination, with a propeller-shaft, of a series of propeller-blades mounted on hubs thereon, each blade having a base provided with teeth, and adapted to be held but capable of turning upon the hub, a roller for covering each base upon the hub and adapted to admit racks to engage the teeth upon the bases of the blades, the racks being extended from one screw-propeller to another parallel with the shaft through the hubs of the collars, and means for moving the racks five and six to turn the blades upon all the propellers simultaneously through the desired arc.

700,979. WIRE-SWINGING MACHINE. BRADIS E. WHELEY, Lynn, Mass. Filed Dec. 13, 1900. Serial No. 30,701. (No model.)

Claim.—1. A web-coring machine, having, in combination, stitch-forming mechanism, a web-guide, and a web-holder constructed and arranged to move with the shoe and to hold the end of the web in contact with the upper, substantially as described.

2. A web-coring machine, having, in combination, stitch-forming mechanism, a web-guide, and a web-holder constructed and arranged to move with the shoe and to hold the end of the web in contact with the upper, substantially as described.

3. A web-coring machine, having, in combination, stitch-forming mechanism, a web-guide, a web-holder constructed and arranged to move with the shoe and to hold the end of the web in contact with the upper, and means for automatically throwing the web-holder out of operative position after a predetermined number of operations of the stitch-forming mechanism, substantially as described.

4. A web-coring machine, having, in combination, stitch-forming mechanism, a web-guide, a web-holder constructed and arranged to move with the shoe and to hold the end of the web in contact with the upper, means under the control of the operator for moving said web-holder into operative position and means for automatically throwing said web-holder out of operative position after a predetermined number of operations of the stitch-forming mechanism, substantially as described.

5. A web-coring machine, having, in combination, stitch-forming mechanism, a web-guide, a web-holder constructed and arranged to move with the shoe and to hold the end of the web in contact with the upper, and means for moving the web-holder into and out of operative position, substantially as described.

6. A web-coring machine, having, in combination, stitch-forming mechanism including a needle, a web-guide on one side of the needle and a web-holder on the opposite side of the needle, substantially as described.

700,980. APPARATUS FOR UNLOADING VEHICLES. OTIS H. WOODWORTH, Buffalo, N. Y. Filed Nov. 27, 1901. Serial No. 61,899. (No model.)

Claim.—1. A vessel having its hold provided in its bottom with discharge-openings, gates applied to said openings, a permanent secondary bottom arranged between the bottom of the hold and the main bottom of the hull and forming with the latter bottom an intervening water-chamber, a tunnel or tunnels arranged in said water-chamber underneath said discharge-openings, and a discharge conveyor or conveyors arranged to pass through said tunnel or tunnels, substantially as set forth.

2. A vessel having its hold provided with a hopper-bottom containing discharge-openings, gates applied to said openings, a permanent secondary bottom arranged between said hopper-bottom and the main bottom of the hull and forming with the latter an intervening water-chamber, walls or partitions extending lengthwise through said water-chamber on opposite sides of said discharge-openings, and forming a discharge tunnel or tunnels, said tunnel or tunnels having an inclined end portion which rises above the water-line and opens through the end of the vessel, and a conveyor or conveyors arranged in said tunnels, substantially as set forth.

3. A vessel having its hold provided with a hopper-bottom containing discharge-openings which are located on opposite sides of the hold, gates applied to said openings, a permanent secondary bottom arranged between said hopper-bottom and the main bottom of the hull and forming with the latter a water-chamber, a main central head extending through the height of said water-chamber, and two pairs of walls arranged on opposite sides of said head and extending from the main to the second-

ary hull-bottom and forming discharge-tunnels, said tunnels being located underneath the discharge-openings of the hopper-bottom, and conveyors arranged in said tunnels, substantially as set forth.

700,981. PARACHUTE-KITE. OLIVER V. WYATT, Marlow, Ind. Filed Mar. 2, 1902. Serial No. 66,467. (No model.)

Claim.—1. As a new article of manufacture, an attachment for a kite-string consisting of a wire loop adapted to be connected into the string and having a laterally-extended switch-arm disposed to cause articles carried upon said string to be automatically released therefrom, substantially as described.

2. Is an attachment for kite-strings, a wire loop having means for connection into the path of the string and with a rearwardly-extending loop-band disposed to support the string, a switch-arm extending forwardly and forming a continuation of said loop-band and projecting laterally from said loop, whereby the string is supported, and means provided for guiding articles from said string upon said switch-arm, substantially as described.

3. Is an attachment for the kite, a wire loop adapted to be connected into the string and having a laterally-extended switch-bar, a toy having an open hook disposed to engage the kite-string and adapted to be conducted upon said switch-bar and to be discharged therefrom, substantially as described.

4. Is an attachment for kite-strings, a wire loop having means for connection into the path of the string, a rearwardly-extending loop-band disposed to support the string, a switch-arm extended forwardly of said loop-band and forming a continuation thereof and projected laterally from said loop, and toys having hooks disposed to engage said string, and adapted to be conducted upon and discharged from said switch-bar, substantially as described.

700,982. SPRAYING DEVICE. HERBERT REINHARDT and JAMES REINHARDT, Brooklyn, N. Y. Filed Feb. 2, 1901. Serial No. 61,816. (Model.)

Claim.—1. A device of the class herein described comprising a liquid-receptacle having its bottom arranged at an angle to the side walls thereof; a delivery-tube within said receptacle and held against movement with respect thereto, the said tube projecting somewhat outwardly from said receptacle at the top thereof and terminating in a single delivery end; means whereby communication between the opposite end of said delivery-tube and variable points along and contiguous to the apex of the angle aforementioned of said receptacle, is established; and a one-nozzle air-pump situated to deliver air under pressure at the delivery end of said delivery-tube.

from said receptacle at the top thereof and terminating in a single delivery end; means whereby communication between the opposite end of said delivery-tube and variable points along and contiguous to the apex of the angle aforementioned of said receptacle, is established; and a one-nozzle air-pump situated to deliver air under pressure at the delivery end of said delivery-tube.

2. A device of the class herein described comprising a liquid-receptacle having its bottom portion arranged at an angle to the side walls thereof; a main delivery-tube within said receptacle, the said tube having its delivery end projecting somewhat outwardly from the liquid-receptacle, and having at its opposite end a plurality of minor members, the latter all communicating with said main delivery-tube and situated so that the intake ends thereof will occupy variable points along and contiguous to the apex of the angle aforementioned of said receptacle; and an air-pump situated to deliver air under pressure at the delivery end of said main delivery-tube.

3. A device of the class herein described comprising a liquid-receptacle having its bottom portion arranged at an angle to the side walls thereof; a delivery-tube within said receptacle, the said tube having its delivery end projecting somewhat outwardly from the liquid-receptacle, and having its opposite end branched and arranged to receive the contents of said receptacle at variable points along and contiguous to the apex of the angle aforementioned of said receptacle; and an air-pump situated to deliver air under pressure at the delivery end of said delivery-tube.

4. A device of the class herein described comprising a liquid-receptacle having its bottom portion arranged at an angle to the side walls thereof; a main delivery-tube within said receptacle, the said tube having its delivery end projecting somewhat outwardly from the liquid-receptacle, and having at its opposite end a plurality of branched minor members, the latter all communicating with said main delivery-tube and situated so that the intake ends thereof will occupy variable points along and contiguous to the apex of the angle aforementioned of said receptacle; and an air-pump situated to deliver air under pressure at the delivery end of said main delivery-tube.

5. A device of the class herein described comprising a liquid-receptacle having its bottom arranged at an angle to the side walls thereof; a delivery-tube within said receptacle and held against movement with respect thereto, the said tube projecting somewhat outwardly from the liquid-receptacle at the top thereof and terminating in a single delivery end; means whereby communication between the opposite end of said delivery-tube and variable points along and contiguous to the apex of the angle aforementioned of said receptacle, is established; and a one-nozzle air-pump situated to deliver air under pressure at the delivery end of said delivery-tube.

700,988. HAT-PARING MACHINE. BLANK & ALVORD, Danbury, Conn., assignors of one-half to Michael J. Dayin, Danbury, Conn. Filed Sept. 25, 1901. Serial No. 70,051. (No model.)

Claim.—1. In a hat-paring machine, the combination of a stationary foot, means for maintaining the curled hat-brim in constant contact with said foot, the rotary cutter, and means for advancing and retracting said cutter at predetermined times and in direct proportion to the varying width of the curl of the hat-brim, substantially as set forth.

2. In a hat-paring machine, the combination of a stationary foot, means for revolving the hat in a predetermined oval circuit, whereby constant contact is maintained between said foot and the curl of the brim, the outer-supporting carriage, the cutter journaled in said carriage, means for revolving said cutter, and means for reciprocating said carriage simultaneously with the revolution of the hat and to a degree predetermined by the varying width of the curl of the hat-brim, substantially as set forth.

3. In a hat-paring machine, the combination of the stationary foot, the rotary cutter, means for reciprocating said cutter to a degree predetermined by the varying width of the curl of the hat-brim, means for supporting the hat and for revolving the same in an oval circuit predetermined by the general oval shape of the brim whereby said brim is maintained in constant contact with said foot, and means for varying the plane of the revolution of the hat whereby the raised sides and depressed ends of the brim are acted upon by the cutter in the same horizontal plane, substantially as set forth.

4. In a hat-paring machine, the combination of a stationary foot, means for revolving the hat in an oval circuit predetermined by the general oval shape of the brim whereby all parts of the curl of the brim are presented to said foot in the same vertical plane, means for tilting the hat upwardly and downwardly during its revolution whereby the ends and sides of the curled brim are maintained in the same horizontal plane when presented to said foot, the cutter, and means for advancing and retracting said cutter during the revolution of the hat and in a degree predetermined by the varying width of the curl of the brim, substantially as set forth.

5. In a hat-paring machine, the combination of the stationary foot, the rotary shaft composed of gimbal-jointed sections and having its two upper members inclined in opposite directions, the hat-block carried by the uppermost member, means for swaying said shaft in opposite directions during its revolution whereby the hat will be revolved in an oval circuit and the curled brim maintained in constant contact with said foot, and a cutter having a variable reciprocation during the paring operation, substantially as set forth.

6. In a hat-paring machine, the combination of the stationary foot, the shaft 32 normally inclined away from said foot and carrying at its upper end the hat-block, the vertical shaft 71, the shaft 80 inclined to-

ward the vertical cross-plane of said foot and having its ends gimbal-jointed respectively with the shafts 83 and 71, the cam carried by the shaft 80, the stationary bracket 84, means for resiliently keeping said cam normally in contact with a plane surface of said bracket whereby the revolution of said shaft will cause the hat to be swayed in a plane substantially parallel with the vertical cross-plane of said foot, the hand-lever revolved to the shaft 71, the carriage depending rigidly from said lever and capable of tilting and reciprocating movements, the friction-roller supported by said carriage, the cam carried by the shaft 71, and the spring whereby said roller is maintained in contact with said cam, whereby the revolution of said shaft will cause the hat to be swayed in a plane substantially at right angles to the vertical cross-plane of said foot, substantially as set forth.

7. The combination of a series of gimbal-jointed shafts, one end shaft being engaged with power-transmitting means while the other end shaft supports the hat, and means for swaying the hat-supporting shaft in opposite planes, substantially as set forth.

8. The combination of the rotary shaft incapable of any swaying movement, the cam carried by this shaft, the oppositely-inclined shafts connected with each other and with the first-mentioned shaft by gimbal-joints, the hat-support on the upper shaft, the cam carried by the middle shaft, means for resiliently maintaining this cam against a stationary surface, the lever revolved to the top shaft, the carriage secured to and depending from said lever, the rollers supported by said carriage, the horizontal guide-rods between which said rollers and carriage extend, and means for maintaining a constant resilient contact between one of these rollers and the first-mentioned cam, whereby combined rotary and swaying movements are given to the hat, substantially as set forth.

9. In a hat-paring machine, the stationary foot cut away as described and gradually tapering down to a thin edge at the extreme front, in combination with means for keeping the curl of the hat-brim always hooked over said foot and in close contact therewith, the rotary cutting-tool journaled in a swiveling carriage immediately above said foot and adapted to pierce the curl of the brim when said carriage is lowered and capable of operating within the cut-away portion of said foot, and means for advancing and retracting said carriage to a degree determined by the varying width of the curl of the brim, substantially as set forth.

10. The combination of the shaft 71, the cam carried thereby, the stationary guide-rods one of which is provided with rack-teeth, the carriage having outer and taper rollers depending between said rods, the spring whereby the lower roller is normally kept in contact with said cam, and the pawl capable of sliding on said rack-teeth, whereby when said pawl is moved outwardly and engaged with said teeth the lower roller will be held beyond the field of said cam, substantially as set forth.

700,984. PROCESS OF MORDANTING ANIMAL FIBER. OTTO F. ARNER, New York, N. Y. Filed Mar. 4, 1900. Serial No. 672,000. (No specimens.)

Claim.—1. In the production of a mordant on animal fiber for dyeing, the process of treating the fiber with a solution of free chromic acid, the treatment taking place at such temperature as will not of itself substantially produce an oxidation of the fiber under treatment.

2. The process of producing a mordant on animal fiber for dyeing, which consists in first treating the fiber with a solution of free chromic acid, and, second, in thereafter treating the fiber with a suitable reducing agent, the treatment taking place at such temperature as will not of itself substantially oxidize the fiber under treatment.

700,985. WIRE-STRETCHER. JAMES V. ASHMORE, Clinton, N.Y. Filed Dec. 12, 1901. Serial No. 26,000. (No model.)

Claim.—1. A wire-stretcher comprising a support, a lever fulcrumed on the support, the longitudinally-arranged beam provided with means for engaging a fence-wire, the short and long reciprocating bars connecting the inner and outer beams with the lever and pivoted to the latter at opposite sides of the fulcrum thereof, and guides extending from the support and from the inner bar and receiving the long reciprocating bar, substantially as described.

2. A wire-stretcher comprising the beams arranged in alignment and each provided with a movable wall-section pivoted at one end and arranged to swing outward, a latching device for latching the other end of the wall-section, a lever fulcrumed on the support, and bars connected with the beams and with the lever, substantially as described.

3. A wire-stretcher comprising a support, a lever fulcrumed thereon, the longitudinally-arranged beams having movable wall-sections, spring-actuated clamping-degs mounted within the beams and having chains or handle portions extending through slots thereof, bars connecting the beams with the lever, and a clamp connected with the support, substantially as described.

700,986.

700,986. LEO MEASUREMENT AND REDUCTION. RUSSELL L. ARNER, Fayetteville, W. Va. Filed May 24, 1902. Renewed Apr. 17, 1903. Serial No. 126,301. (No model.)

Claim.—In a manner-gage, the combination, with a two-part casing, each part of which is provided with a room, of a train of gearing in one of the rooms, one end of which is provided with a spur-wheel which extends through the wall of the room in position to be in engagement with the lumber being measured, a shaft at the other end of the train of gearing projecting through the bottom of the room in the other part of the casing, a toothed wheel and a pointer on the projecting end of said shaft, a catch for engaging with the toothed wheel, the free end of which projects through the side of the casing, a dial under the pointer, and a spring for returning the toothed wheel and pointer to their normal position, substantially as described.

700,987. AUTOMATIC VEHICLE-BRAKE. JAMES E. ARNER, Caldwell, Minn. Filed Apr. 6, 1901. Serial No. 54,978. (No model.)

Claim.—1. In an automatic vehicle-brake, the combination with a sliding draft-bar, of a brake-beam carrying shoes, springs holding said brake-beam with the shoes in engagement with the wheels, the over-levers, an operative connection between one end of said levers and the brake-beam, forwardly-extending rods pivotedly connected with the other end of said levers, a coupling-bar movable upon the tongue of the vehicle and to which the rods are connected at their opposite ends, and to which the draft-bar is pivotedly connected, substantially as described.

2. In an automatic vehicle-brake, the combination of straps secured to the rear ends of the beams and projecting rearwardly therefrom a brake-beam movable in said straps and carrying brake-shoes, springs connected at their respective ends to the ends and mid brake-beam, a rearwardly-extending arm centrally secured to the cross-bar of the beams, levers intermediate pivoted to said arm, links connecting one end of said levers, to the brake-beam, operating-rods pivotedly connected to the opposite ends of said levers and extending forwardly, a coupling-bar to

which the forward ends of the rods are connected, and a sliding draft-bar mounted upon said coupling-bar, substantially as described.

3. In an automatic vehicle-brake, the combination with the slotted tongue and draft-bar, of a coupling-iron having a stem projecting through the slot in the tongue and also through the draft-bar, a slotted strap or plate attached to the tongue and extending across the draft-bar, a slotted plate arranged upon the slotted strap having a link pivotedly connected thereto, a nut secured upon the stem of the coupling-iron and adapted to hold the slotted plate in place upon the slotted strap, a lever connected to the link, the rods connected to the rear end of the coupling-iron, spring-actuated brake-beams, the levers connected to the said brake-beams and to the operating-rods, substantially as set forth.

700,988. AUTOMATIC LEADER FOR TYPE-SETTING MACHINES. JOHN S. BARNETT and MARSH C. DRAKE, Philadelphia, Pa., assignors, by mesne assignments, to Lanston Monotype Machine Company, Washington, D. C., a Corporation of Virginia. Filed Nov. 9, 1901. Serial No. 81,716. (No model.)

Claim.—1. A controller for type-composing machines provided with special leading-signals for controlling the insertion of leads; substantially as described.

2. A controller for type casting and composing machines provided with leading-signals compounded of justification-designating signals and a selected signal; substantially as described.

3. In a type-composing machine provided with line-assembling devices and a controller, and in combination therewith a leading mechanism responsive to signals contained in the controller and governed thereby; substantially as described.

4. In a type-composing machine the combination with the line-assembling devices, of a leading mechanism and a controller in the form of a perforated record-strip, the latter governing the action of said leading mechanism; substantially as described.

5. In a type casting and composing machine governed in action by a perforated record-strip, the combination with said record-strip and the galley or line-assembling mechanism, of a leading mechanism provided with controlling devices responsive to said record-strip, substantially as described.

6. In an automatic type casting and composing machine whose action is governed by a controller, the combination with the line-assembling or galley mechanism and a controller, of an automatic leading mechanism provided with means for throwing it into and out of action, and device responsive to selected signals of the controller acting upon said leading mechanism to automatically govern the delivery of leads to the galley; substantially as described.

7. In an automatic type casting and composing machine the combination of the following elements, to wit: a controller provided with signals representing justification and leads; a galley mechanism responsive to the justification-signals; and a leading mechanism deriving motion from the galley mechanism and controlled, as to operation, by the lead-signals of the controller; substantially as described.

8. In an automatic type casting and composing machine the combination of the following elements, to wit: a controller provided with justification and lead-signals; a galley mechanism responsive to the justification or lead-signals; and a leading mechanism responsive to the lead-signals or justification signals but deriving its motion from the galley mechanism; substantially as described.

9. In a type-composing machine the combination of the following elements, to wit: a controller provided with lead-signals in addition to the normal signals; a galley or composing mechanism for assembling lines of type; a leading mechanism; means for actuating said leading mechanism; and means governed by the controller for automatically interrupting or discontinuing the leader-extending device at a period subsequent to the delivery accompanying the lead-signal; substantially as described.

10. In a galley mechanism for type-composing machines the com-

bination with the galley, and line-transferer, of a movable galley-blade normally closing the entrance to the galley and provided with a longitudinal channel, a lead-feeder delivering into said channel, and a pusher working in said channel to transfer the lead to the galley; substantially as described.

11. In a galley mechanism for type-composing machines, the combination with the galley, line-carrier and line-transferer, of a galley-blade movable substantially perpendicular to the path of the line-transferer and provided with a longitudinal channel, a lead-feeder device discharging into said galley-blade, and a pusher moving in unison with the line-carrier to advance a lead opposite the galley as the line-carrier returns after delivering a line to the galley; substantially as described.

12. In a lead-feeding mechanism for type-composing machines the combination with the lead receptacle or channel and a pusher for discharging the leads therefrom, of a cut-off located opposite the discharge-opening and comprising a bar supported to move outwardly and upwardly under the pressure of the lead being discharged and held in contact therewith by spring-pressure so as to prevent the escape of superposed leads; substantially as described.

13. In a lead-feeding attachment for type-composing machines the combination with a lead receptacle or channel provided with a discharge orifice or slot and a shouldered pusher working therethrough and engaging the lowermost lead, of a cut-off supported on links to move both vertically and outwardly with respect to the discharge-orifice and provided with an elastic tension member holding it toward said discharge-orifice; substantially as described.

14. In a lead-feeding attachment for type-composing machines the combination, to form an adjustable lead holding and feeding attachment, of the following elements, to wit: a bed-plate; two flanged bearings or uprights of which one is adjustably secured to the bed-plate and each is provided with a transverse bar forming the bottom of the lead-channel; a discharge-orifice immediately above said bar; a shouldered pushing-blade attached to a bar supported in guides on each bearing; a pivoted cut-off bar mounted on each bearing; and actuating devices common to the two pushing-blades; substantially as described.

15. In a galley mechanism for type-composing machines the combination with a vertically-reciprocating longitudinally-channelled blade at the entrance to the galley, of a lead-feeder attachment located to one side of the galley and above said blade in position to deliver the leads into the latter; substantially as described.

16. In a galley mechanism for type-composing machines the combination with the vertically-movable longitudinally-channelled blade at the entrance to the galley, of a lead-feeder located to one side of the galley and above said blade for delivering leads to the latter, actuating device for said lead-feeder connected to the galley-blade, and a pusher reciprocating within the galley-blade; substantially as described.

17. In a galley mechanism for type-composing machines the combination with the galley and the lead-feeder, of a galley-blade provided with a longitudinal channel open at the top rear end and for the reception of the leads and open at the bottom at the opposite end for the discharge of the leads, and a pusher working in said channel; substantially as described.

18. In a galley mechanism for type-composing machines, the combination with the channelled galley-blade, of the pusher supported on a way attached to said blade and connected to its driving mechanism through a yielding trip device; substantially as described.

19. In a galley mechanism for type-composing machines the combination with the slide actuating the line-carrier and the reciprocating channelled galley-blade, of a lead-feeder, connected to and operating in unison with the galley-blade, and a lead-transferer working in the galley-blade and connected to and operating in unison with the line-carrier slide; substantially as described.

20. In a lead-feeding attachment for the galley mechanism of a type-composing machine such as described, the combination with the lead-feeder, the pusher mounted and reciprocating upon the galley-blade and the slide for actuating the line-carrier, of the link pivoted at one end to said slide and at the other to said pusher, said two points of attachment being in a line transverse to the direction of motion of the galley-blade, whereby as the latter is elevated the pusher will be rotated slightly; substantially as described.

21. In a lead-feeding attachment for the galley mechanism of a type-composing machine, the combination with the pusher carried by the galley-blade and the slide from which said pusher receives longitudinal motion, of the link pivoted to said slide and provided with a shoulder and a spring-actuated latch for engaging a pin on the pusher; substantially as described.

22. In a type-composing machine whose action is governed by a controller containing leading signals, the combination of a leading attachment or mechanism provided with a switching device for throwing it into or out of action, and an automatic signal-interpreter intermediate said

switching device and the controller, whereby the latter determines the times and intervals of leading; substantially as described.

23. In a type-composing machine, the combination of the following elements, to wit: a leader; actuating device for said leader including a switch for throwing the same into or out of action; a controller; and means for actuating said switch from said controller; substantially as described; whereby the insertion of leads is governed automatically by said controller.

24. In a type-composing machine containing a galley or line-assembling mechanism, and a lead-supplying attachment therefor, the combination with the latter, of actuating devices controlled by a switch, a perforated controller, and a pneumatic signal-interpreter intermediate said switch and the controller; substantially as described.

25. In a type-composing machine the combination of the following elements, to wit: line-assembling device including a galley, a line-carrier, a line-transferer and a galley-blade; a leading attachment for inserting leads between adjacent lines provided with an actuating mechanism including a disengaging device for suspending the action of the leader; a switch adapted to be engaged by the line-carrier mechanism for actuating said disengaging member to stop or start the leader; and means for actuating said switch; substantially as described.

26. In a type-composing machine the combination of the following elements, to wit: a galley or line-assembling mechanism; a lead-feeder provided with actuating means including a disengaging device for throwing the leader into and out of action; a switch-bar for actuating said disengaging device; means for raising the switch; and a movable member—such as arm 112—for engaging the switch to operate the disengaging device; substantially as described.

27. In a type-composing machine the combination with the disengaging device for controlling the action of the lead-feeder, of a switch-bar pivoted to a link on that it can oscillate about either of two centers and provided with two shoulders; a reciprocating member—such as arm 112—for engaging the shoulders on the switch-bar, to reciprocate the latter; and means for tilting said switch-bar to withdraw one of its shoulders from the path of the said reciprocating member; substantially as described.

28. In a type-composing machine the combination of the following elements, to wit: a leader whose actuating device is connected to a driving member through a link capable of both longitudinal and rotary motion; a link partaking of the rotary motion of said link; a switch-bar pivoted to said link and provided with an engaging shoulder at each side of its point of attachment to the link; a reciprocating member—such as bar 112—adapted to engage the shoulders on the switch-bar when projected into its path; and means for tilting said switch-bar to withdraw one shoulder from the path of said member; substantially as described.

29. In a type-composing machine and in combination with the disengaging device of the leader-actuating mechanism, of the switch-bar pivoted to one end of a link and provided with engaging shoulders for co-operating with a movable driving member, such as bar 112, and a clamping-lever pivoted to the switch-bar to one side of the point of attachment to the link and adapted to be projected into the path of the said driving member; substantially as described.

30. In a type-composing machine the combination of the following elements, for interpreting and transmitting signals from the controller to the leader, to wit: a reciprocating primary driving member; a driven member adapted to be coupled with said driving member; a second driving member coupled with the driven member; and means for coupling up the primary driving and driven members, and the second driving member with its driven member; substantially as described.

31. In a type-composing machine the combination of the following elements, to wit: a primary driving member; a driven member adapted to be coupled with said driving member; a plurality of secondary driving members coupled with said driven member; a piston controlling the engagement of the said driven member and the primary driving member; and separate pistons for controlling the engagement of said secondary driving members with their transmitting members; substantially as described.

32. In a type-composing machine, as a means for interpreting and transmitting signals from the controller to the leader, the combination of the following elements, to wit: a primary driving member—such as pin P2; a driven member adapted to be coupled to said driving member—such as through link 84; a plurality of secondary driving members—such as links 82—coupled to said driving member; pistons controlling the engagement of said driven and secondary driving members; and an oscillating transmitting member—such as cross-head 73—with which said secondary driving members co-operate; substantially as described.

33. In a type-composing machine, the combination with the leader-controlling device, of a pivoted cross-head, two reciprocating members—such as links 82—normally disconnected from said cross-head but each

provided with means for shifting it into engagement therewith; a reciprocating driver and a driven member—such as link 84—normally disconnected from said driver and provided with means for shifting it into engagement therewith and for transmitting motion to the two reciprocating members.

34. In a type-composing machine, as a means for transmitting signals from the controller to the leader, the combination of the following elements, to wit: an oscillatory cross-head whose arms are provided with retaining catches; three links connected to reciprocating members; a driving member; and a plurality of pistons, one for each link, operating through the links to connect the one to the driving member and the others to engage the catches and shift the position of the cross-head; substantially as described.

35. In a type-composing machine the combination of the following elements, to wit: an oscillatory cross-head; a reciprocating link opposite each arm of the cross-head and movable into and out of engagement therewith; a reciprocating driving member overlying said links and forming a stop therefor; a third link detachably connected to said driving member and connected to the first-mentioned links through a yielding connection; and means for independently shifting each of said links from normal position into engagement with their opposing members; substantially as described.

700,289. RECORD-STRIP-FEEDING MECHANISM. JOHN S. RANNEY, Philadelphia, Pa., assignor, by mesne assignments, to Lanston Monotype Machine Company, Washington, D. C., a Corporation of Virginia. Filed Dec. 2, 1901. Serial No. 61,717. (No model.)

Claim.—1. In a record-strip-feeding mechanism the combination with the feeding device engaging the strip to advance the latter, of a supply-spool provided with leads and a concave holder provided with shoulders for positioning the spool, the periphery of the heads of said spool being maintained by gravity in frictional contact with said holder; substantially as described.

2. In a record-strip-feeding mechanism the combination with the strip-feeding device, of a concave trough or receptacle where and pieces are cut away to fit the side pieces of the frame and provided with heads engaging bearings in the frame; substantially as described.

3. In a record-strip-feeding mechanism, the combination with the strip-feeding device, of a winding-spool and actuating device therefor including a motor-spring and a tension-restorer, the latter reciprocating in unison with the feeding device, to restore the initial tension of the spring for each feed movement; substantially as described.

4. In a record-strip-feeding mechanism the combination with strip-feeding device, and a winding-spool, of actuating mechanism for said spool, the same including a ratchet, a motor-spring for advancing the spool, and a retarding device actuated by the feeding device, to restore the initial tension of the motor-spring after each advance of the feeding device; substantially as described.

5. In a record-strip-feeding mechanism the combination with record-strip-feeding device and a winding-spool of actuating device for said spool, the same comprising a ratchet-wheel, a pawl, a motor-spring for advancing said pawl, an arm connected to the feeding device and reciprocating in the path of the pawl-carrier, said arm being located in advance of the pawl-carrier and engaging the latter to move it in opposition to the motor-spring; substantially as described.

6. In a record-strip-feeding mechanism the combination of the following elements, to wit: a spring-actuated center-pin; a revolvable head having a center bearing in alignment with said pin and one or more locking-perforations to one side of said center bearing; a spool provided with a journal-bearing to receive said center-pin and a spring-actuated reel mounted

ed within the spool and provided with a center-pin and a locking-pin; substantially as described.

7. In a record-strip-feeding mechanism the combination with the frame, the spring-actuated center-pin, the rotary head, and the spool provided with a bearing in one end and a reel provided with a center-pin and locking-pin movable through the opposite end of the spool, of the guides fixed to the frame and curving to position the spool preliminary to the entrance of the center-pin and movement of the reel into engagement with the rotary head; substantially as described.

8. As a new article of manufacture a winding-spool for record-strip-feeding mechanisms, the same comprising a tubular body provided at one end with a center bearing, a reel provided at one end with a center-pin and a locking-pin resting in apertures in one head of the body, while the opposite end of the reel comprises the center bearing in the other end of the body, and a spring engaging said reel to hold it retracted within the body; substantially as described.

700,290. PUMP-ACTUATING MECHANISM FOR TYPE-SETTING. JOHN S. RANNEY, Philadelphia, Pa., assignor, by mesne assignments, to Lanston Monotype Machine Company, Washington, D. C., a Corporation of Virginia. Filed Dec. 2, 1901. Serial No. 61,648. (No model.)

Claim.—1. In a metal-injecting mechanism such as described, the combination with the pump-cylinder and piston-rod, each provided with rollers or shoulders, of the actuating-lever and the slides pivoted to said levers and engaging the rollers on the pump-cylinder and piston-rod respectively; substantially as described.

2. In a metal-injecting mechanism such as described, the combination with the cylinder and piston-rod and the connected forced actuating-levers of the sheet fitted to transverse guides on the cylinder and piston-rod, respectively, and each provided with a conical radial recess and central pin engaging a conical radial bearing and central recess on one branch of each actuating-lever; substantially as described.

3. In a metal-injecting mechanism such as described, the combination with the cylinder, piston-rod and actuating-levers therefor, of the guides applied to the cylinder and engaging the piston-rod to resist lateral motion; substantially as described.

4. In a metal-injecting mechanism, such as described, the combination with the piston-rod and cylinder of the pump and the connected actuating-levers whose forced engaging ends embrace the cylinder and piston-rod, respectively, and engage opposite collars thereon, of guides carried by the cylinder in the plane of movement of the forced engaging ends of the levers, said guides engaging the piston-rod on opposite sides thereof beyond the cylinder; substantially as described.

700,291. RECORD-STRIP-FEEDING MECHANISM OF AUTO-MATIC TYPE-CASTING OR OTHER MACHINES. JOHN S. RANNEY, Philadelphia, Pa., assignor, by mesne assignments, to Lanston Monotype Machine Company, Washington, D. C., a Corporation of Virginia. Filed Dec. 2, 1901. Serial No. 61,648. (No model.)

Claim.—1. In a record-strip-feeding mechanism the combination with the cross-bar, pin-wheels and air-bar, of two tension-rollers, the one in front and the other in rear of the cross-bar and both gravitating toward said cross-bar; substantially as described.

2. In a record-strip-feeding mechanism the combination with the cross-bar, feed-wheels and air-bar, of two tension-rollers, one in front and the other in rear of the cross-bar, said rollers being supported to gravitate toward the cross-bar at points below the axis of the feed-wheels; substantially as described.

3. In a record-strip-feeding mechanism the combination with the cross-bar, feed-wheels and movable air-bar, of two gravitating tension-rolls located on opposite sides of the cross-bar and supported so as to permit lateral displacement of either or both ends under the action of the record-strip, substantially as described.

4. In a record-strip-feeding mechanism the combination with the feeding device and cross-bar and the air-bar movable toward and from the latter, of two levers pivoted upon the air-bar and each supporting a roller in position to engage the record-strip on one side of the feeding device; substantially as described.

5. In a record-strip-feeding mechanism the combination with the pivoted air-bar, of two supplemental tension-rolls and levers for said rolls each comprising two independent supporting-plates separately and adjustably pivoted upon the air-bar, to permit lateral displacement of each roll at either end thereof; substantially as described.

6. In a record-strip-feeding mechanism the combination with the cross-bar feed-wheels and laterally-movable air-bar, of feeding or supplemental tension-rolls each loosely journaled in a hanger pivotally connected to the air-bar at a point intermediate the front and rear walls of the air-bar, whereby said rolls are caused to approach by gravity to exert pressure upon the record-strip and to yield laterally at either end, substantially as described.

7. In a record-strip-feeding mechanism the combination with the pivoted air-bar, of a plate detachably applied thereto, a rod supported on said plate, a dependent hanger pivotally attached to said rod at a point to one side of the axis of the air-bar, a roll mounted in said hanger, and a link or links pivotally connected to the frame and hanger and operating to swing the latter upon its supporting-rod as the air-bar is withdrawn from the cross-bar; substantially as described.

8. In a record-strip-feeding mechanism the combination with the pivoted air-bar, of a plate detachably applied thereto, a rod supported on said plate, a dependent hanger pivotally attached to said rod at a point to one side of the axis of the air-bar, a roll mounted in said hanger, and a link or links pivotally connected to the frame and hanger and operating to swing the latter upon its supporting-rod as the air-bar is withdrawn from the cross-bar; substantially as described.

9. In a record-strip-feeding mechanism the combination of the following elements, to wit: a cross-bar; feed-wheels; a pivoted air-bar; two levers, each carrying a tension-roll, dependent from and pivotally attached to the air-bar, one of said levers extending over the air-bar in position to be engaged by the latter when moved away from the cross-bar; and a link or links connecting the opposite lever to the frame in a manner to cause its elevation when the air-bar is retracted; substantially as described.

10. As a new article of manufacture a supplemental tension attachment for record-strip-feeding mechanism such as described, the same comprising a bed-plate or frame adapted for attachment to a pivoted air-bar on its supports; a rod mounted on said frame; two levers pivotally suspended from said rod and each comprising two independent plates provided with open bearings for the reception of a roll; a rod engaging enlarged openings in the plates constituting one of said levers; links engaging said last-named rod; and another rod engaging said links and adapted to engage bearings on the frame forming the support for the air-bar to which the attachment is to be applied; substantially as described.

700,992. RACE-GOOD PARTNER. PAUL R. GOOD, San Francisco, Cal. Filed Dec. 10, 1901. Serial No. 65,512. (No model.)

Claim.—1. The herein-described rack-and-pinion formed of a single piece of metal comprising a U-shaped body having a central aperture

in the bottom; side portions extending perpendicularly to the bottom part and having spurs on their outer ends projecting laterally; and prongs on the sides of the body beyond the side portions, standing upwardly in planes parallel with the side portions.

2. The herein-described blank, having the following parts integral with one another: the body part having the central aperture *a*, the cross *d*, terminating in pointed ends; the prongs *e* on the sides of the cross; and the prongs *g*; said parts forming when bent a U-shaped structure, substantially as described.

700,998. MACHINE FOR GRINDING KNIVES, PRINCIPALLY THOSE OF SAUSAGE-MACHINES OR THE LIKE. OTTO BERNER, Berlin, Germany. Filed Apr. 2, 1901. Serial No. 66,045. (No model.)

Claim.—1. In a machine for grinding knives of the class described, the combination with a grinding-wheel, means for displacing said wheel in an axial direction and means for revolving said wheel, of a knife-holder consisting of a disk revolvably mounted at an angle to the grinding-wheel, means for moving said disk in a longitudinal and transverse direction, means for limiting the movement of said disk, means for holding said disk against revolution in the desired position, and means for adjustably holding the knife to be ground on said disk, substantially as described.

2. In a machine for grinding knives of the class described, the combination with a grinding-wheel, means for displacing said wheel in an axial direction and means for revolving said wheel, of a knife-holder consisting of a disk revolvably mounted on a support, means for moving said support in a longitudinal and transverse direction, a stop for limiting the movement of said support, a bolt adapted to engage holes in said disk for holding the latter against revolution in the desired position, a right and left handed screw in said disk, clamping-screws on said screw, the jaws of which project beyond the surface of the disk and engage and adjustably hold the knife to be ground substantially as described.

3. In a machine for grinding knives of the class described, the combination with a grinding-wheel, a shaft carrying said wheel, means for displacing said wheel and shaft in an axial direction, consisting of a lever pivoted eccentrically to a disk, and a shaft carrying said disk, said shaft being geared in a shaft carrying an operating-wheel, and means for rotating the grinding-wheel/shaft, consisting of a pulley thereon, connected in said operating-wheel, of a knife-holder consisting of a disk revolvably mounted on a support, and at an angle to the grinding-wheel, means for moving said support in a longitudinal and transverse direction, a stop for limiting the movement of said support, a bolt adapted to engage holes in said disk for holding the latter against revolution in the desired position, a right and left handed screw in said disk, clamping-screws on said screw, the jaws of which project beyond the surface of the disk and engage and adjustably hold the knife to be ground, substantially as described.

700,994. TANK-RAISER. EMERY E. BROWN, Haverbury, and ALBERT L. GUYTON, Boston, Ind. Filed Feb. 17, 1902. Serial No. 64,490. (No model.)

Claim.—1. In the tank-raiser described, the combination with the body comprising the combustion-chamber, the air-inlet line rising from one end of the combustion-chamber, the air-outlet line of larger diameter than the inlet-line rising from the opposite end of the combustion-chamber and connected by the opening *d* with the interior thereof, and the horizontal flange communicating with the air-inlet line and extending therefrom into the combustion-chamber and having discharge-apertures in their inner sides adjacent to their free ends; of the water-receptacle disposed in the combustion-chamber, pipes leading from said receptacle through the body and designed for the passage of water to and from

the receptacle, a burner disposed in the combustion-chamber, below the water-chamber and in a plane between the discharge-apertures of the horizontal air-supply tubes, and the damper normally occupying the opening *d* and having the aperture *f* in its upper portion.

2. In the tank-raiser described, the combination with the body comprising the combustion-chamber, the air-outlet line communicating with the interior of and rising from one end of the combustion-chamber, the air-inlet line rising from the opposite end of the combustion-chamber, and the horizontal flange communicating with the air-inlet line and extending therefrom into the combustion-chamber and having discharge-apertures in their inner sides adjacent to their free ends; of the water-receptacle disposed in the combustion-chamber, pipes leading from said receptacle through the body and designed for the passage of water to and from the receptacle, and a burner disposed in the combustion-chamber below the water-chamber and in a plane between the discharge-apertures of the horizontal flange.

700,995. FOUR-STROKE PETROLEUM-MOTOR. EDWARD A. BENTLEY, Stockholm, Sweden. Filed Apr. 2, 1901. Serial No. 64,982. (No model.)

Claim.—1. In a hydrocarbon-motor, in combination, inlet and exhaust valves, a device in control each of said valves, axially-shiftable means to operate said device and means to retard the action of the inlet-valve, to automatically increase the quantity of hydrocarbon vapor to form an explosive mixture richer in hydrocarbon, substantially as described.

2. In a hydrocarbon-motor, in combination, inlet and exhaust valves, a device to control each of said valves, axially-shiftable means to operate said device, means to simultaneously admit air and hydrocarbon, and means to throttle the inlet-valve and thereby automatically control the means for the admission of air and hydrocarbon, substantially as described.

3. In a hydrocarbon-motor, in combination, inlet and exhaust valves, a lever acting on each valve, axially-shiftable means operating said levers and means to shift the same, a vaporizer external to the engine and communicating with the inlet-valve, means operated from the cam-shifting means to additionally lead the inlet-valve and an auxiliary valve to admit both air and hydrocarbon to the vaporizer, automatically operated by the degree of vacuum and controlled by the inlet-valve to automatically proportion the air and hydrocarbon, substantially as described.

4. In a hydrocarbon-engine, in combination, inlet and exhaust valves, means surrounding them, a driven cam-shaft axially shiftable, means thereon shiftable under the lever controlling the exhaust-valve, whereby said valve can be held open, opened at every other stroke and opened at every fourth stroke and means to vary the lead on the inlet-valve.

5. In a hydrocarbon-engine, in combination, an inlet and an exhaust valve, and a valve controlling gas under pressure, means controlling them, a driven cam-shaft axially shiftable, means thereon to operate the inlet, exhaust and pressure-gas valves, and hand-operated means to additionally lead the inlet-valve and shift the cam-shaft at will, substantially as described.

6. In a hydrocarbon-engine, in combination, an air-inlet and an exhaust valve, and one controlling gas under pressure, a vaporizer external to the engine and arranged to deliver combustible through the inlet-valve simultaneously with air, a valve in the vaporizer controlling the simultaneous inlet of hot air and liquid hydrocarbon and operated by motion, a driven cam-shaft axially movable, means for varying the lead on the inlet-valve and for shifting the cam-shaft to cause the engine to operate on a two or four stroke cycle, or to maintain the exhaust-valve open, substantially as described.

7. In a hydrocarbon-engine, in combination, a spring-held air-inlet valve and an exhaust-valve, and one controlling gas under pressure, a vaporizer external to the engine and arranged to deliver combustible through the inlet-valve simultaneously with air, a valve in the vaporizer controlling the simultaneous inlet of hot air and liquid hydrocarbon, and operated by motion, a driven cam-shaft axially movable, a rack connected to said shaft, a pinion in gear therewith, a hollow shaft secured to the pinion, a hand-lever arranged to rotate the shaft, a collar on the shaft operated by the hand-lever, and a lever pivoted to take under said collar and additionally lead said valve when the collar is depressed, substantially as described.

700,996. MACHINE FOR SPLITTING BARK-STRIPS. EDWARD L. BROWN, Martinsville, Ind. Filed June 24, 1901. Serial No. 65,573. (No model.)

Claim.—1. A reversible cutter beveled on one side to a cutting edge, a guideway having one end adjacent to the beveled side of the cutter and adjustable in its distance from the cutting edge, and reversible feed-disks on the end of a vertically-tilting shaft to feed the material between the bearing-plate and cutter, said feed-disks being automatically adjustable to accommodate material of varying thickness.

2. A table, a reversible vertical shaft projecting through said table, a circular disk mounted on the top of said shaft having its under edge beveled to form an upper cutting edge, a feed-box having one end located under the cutter to hold the material up thereon, means for adjusting said end toward and from the cutter, a horizontal reversible shaft terminating at one end above the feed-box and cutter, said shaft having a vertical rocking adjustment, elevated feed-disks mounted on said end of the horizontal shaft, and yielding means for drawing the end of the shaft having the cutters, down toward the feed-box with a predetermined pressure.

3. In a splitting-machine, a vertical reversible shaft having a cutter at its upper end, a feed-box leading to said cutter, the end of said feed-box forming a bearing for the material under the cutter, a screw for adjusting said bearing end of the feed-box, a horizontal reversible shaft pivoted to afford a vertical adjustment of its lower end, a spring to draw the shaft toward the feed-box, a tension device to regulate the force of the spring, and feeding-disks on the end of the shaft over the feed-box.

700,997. MACHINE FOR CUTTING BARK INTO STRIPS. EDWARD L. BROWN, Martinsville, Ind. Filed June 24, 1901. Serial No. 65,573. (No model.)

Claim.—A frame having a pair of vertical posts, a shaft having a lower end and a fixed pulley mounted on the top of the two posts, a second shaft mounted on said posts below the first shaft, cog-wheels connecting the two shafts, the journal-bases of the second shaft being adjustable vertically, means for holding the adjustment consisting of a threaded bolt

attached to each of the two boxes, one on the bolt and a pair of fixed ears, one on either side of said nut to prevent vertical movement of the nut, a fixed collar on the second shaft circular cutters with washers between each cutter, mounted on the second shaft and a nut on a threaded portion of the second shaft to tighten the cutters and washers against the fixed collar, a board having kerfed end to receive the cutters in the kerf and act as a cleaner to the cutters, a third shaft supported by the posts also having a fixed collar, a metal cylinder mounted on the third shaft against the fixed collar, a nut on a threaded portion of the shaft and washers between the nut and the metal cylinder and inclined tables leading to and from the said cylinder.

700,298. SEAL-LOCK. FERRY BROWN, Wilmington, Del. Filed May 24, 1901. Serial No. 61,750. (No model.)

Claim.—1. In a seal-lock, a hump, means for locking said hump, a seal-mechanism, means comprising a rack and pinion for unlatching said hump and operating said seal-mechanism, substantially as described.

2. In a seal-lock, a hump, a lock thereon, a rotary seal-mechanism, and means comprising a rack and pinion for unlatching said hump and for rotating said seal-mechanism, substantially as described.

3. In a seal-lock, a hump, a lock thereon comprising a bolt, a rotary seal-mechanism, and a pusher for positively rotating said seal-mechanism and withdrawing said bolt, substantially as described.

4. In a seal-lock, a hump, a casing containing a rotary seal-mechanism, a sliding bolt arranged to lock said hump to said casing, and a pusher arranged to positively rotate said seal-mechanism and operate said bolt, substantially as described.

5. In a seal-lock, a hump, a casing containing a rotary seal-mechanism, a sliding bolt arranged to lock said hump to said casing, a pusher arranged to operate said bolt, and a rack and pinion between said pusher and said seal-mechanism, whereby a movement of said pusher to act on the bolt rotates the said seal-mechanism, substantially as described.

6. In a seal-lock, a casing supporting a seal-mechanism, a cover arranged to clamp a seal over said seal-mechanism, and a hump arranged to cover and protect said seal and the aforesaid cover, substantially as described.

7. In a seal-lock, a casing supporting a seal-mechanism and having a projecting ring or rim, a pivoted cover arranged to close over said ring or rim and clamp the seal thereon, and a hump arranged to cover and protect said seal and aforesaid cover, substantially as described.

8. In a seal-lock, a casing containing a seal-mechanism, a pivoted hump arranged to be swung into operative position with said casing, a bolt locking said casing and pivoted hump, and a pusher moving in a path at right angles to the movement of said bolt and arranged to operate said seal-mechanism and withdraw said bolt, whereby the pivoted hump may be swung away from said casing, substantially as described.

9. In a seal-lock, a casing supporting a seal-mechanism and having a bolt-receiving recess therein, a hump carrying a spring-actuated bolt arranged to enter said recess, and a pusher carried by said casing arranged to operate said seal-mechanism and unlock said bolt, substantially as described.

10. In a seal-lock, a casing supporting a rotary seal-mechanism and having a bolt-receiving recess therein, a hump carrying a spring-actuated bolt arranged to enter said recess and lock the hump to the casing, and a pusher carried by the casing and arranged to rotate the seal-mechanism and unlock the bolt, substantially as described.

11. In a seal-lock, a casing supporting a seal-mechanism and having a bolt-receiving recess therein, a hump carrying a spring-actuated bolt arranged to enter said recess, a pusher carried by said casing and arranged to operate said seal-mechanism, and a bolt-operated element between the pusher and the bolt, substantially as described.

12. In a seal-lock, a casing secured to the car-door, and supporting a seal-mechanism and having a recess therein for supporting a way-card, an opening over the seal-mechanism, a cover for clamping a seal over said seal-mechanism, and a hump arranged to be locked to said casing and having eight-openings therein arranged over said recess for the way-card and the seal, substantially as described.

13. In a seal-lock, a casing having a seat for a seal, a seal-mechanism having a pinion contained within the casing and a half carried on the opposite side of the casing, and means for operating said pinion, substantially as described.

14. In a seal-lock, a casing having a seat for a seal, a pinion and means for operating it carried within the casing, one of the trunnions for the pinion projecting through the casing and carrying a seal-mechanism, substantially as described.

15. In a seal-lock, a casing having a seat for a seal, a pinion and means for operating it carried within the casing, one of the trunnions for the pinion projecting through the casing and carrying a seal-mechanism, and a cover arranged to clamp a seal on said seat over the seal-mechanism, substantially as described.

16. In a seal-lock, a casing supporting a seal-mechanism and seal, a recess for a way-card, and a hump having eight-openings exposing said seal and way-card and provided with a flange projecting over the casing to protect the said seal and card, substantially as described.

17. In a seal-lock, a casing containing a seal-mechanism, a hump carrying a bolt for locking said hump to said casing, and a pusher for operating said seal-mechanism and bolt, substantially as described.

700,299. DRAFT-EVENER. EDWARD BROWN, Boring, Iowa. Filed Oct. 30, 1901. Serial No. 59,642. (No model.)

Claim.—1. In a draft-evening, and in combination with a dielectric and equalizing-levers cooperating therewith, bolts of approximately T form having arms at the ends of their cross-heads either to enter the equalizing-levers and prevent pivotal movement thereof or to embrace the edges thereof and limit their pivotal movement, substantially as set forth.

2. In a draft-evening, and in combination with a dielectric, a plate paralleling the dielectric and connected thereto, and equalizing-levers arranged between the dielectric and the said plate, T-shaped bolts pivotally connecting the equalizing-levers with the plate and dielectric and having arms at the ends of their cross-heads either to embrace opposite edges of the said plate and equalizing-levers or to enter corresponding openings formed in the said plate and equalizing-levers, substantially as set forth.

3. A draft-evening comprising a dielectric having a centrally-disposed lug, a plate paralleling the dielectric and spaced therefrom by the said lug, equalizing-levers located between the said plate and dielectric, dielectric applied to the outer ends of the equalizing-levers, a draft-chain having connection with the inner ends of the said equalizing-levers, and T-shaped bolts connecting the equalizing-levers to the said plate and dielectric and provided with arms at the ends of their cross-heads to embrace the edges of the equalizing-levers or to enter corresponding openings in the said plate and equalizing-levers, as and for the purpose set forth.

700,300. ART OF MAKING JUSTIFIED MATRICES. ARTHUR W. CATHAM, Philadelphia, Pa., assignor to Lanston Monotype Machine Company, Washington, D. C., a Corporation of Virginia. Filed Sept. 24, 1901. Serial No. 70,801. (No model.)

Claim.—1. The hereinbefore-described improvement in the art of forming matrices for type and the like which consists in spacing, condensing and hardening the body and face of the blank by pressure, to form and gauge its dimensions and flatten the impression-surface, and subsequently driving the character-punch a determined distance into the flattened surface while the blank is supported on all surfaces except that in which the drive is made.

2. The hereinbefore-described improvement in the art of forming justified matrices for type and the like which consists in subjecting the blank to pressure in an isolating die-cavity containing a punch, to simultaneously form the centering-cavity, flatten the matrix-receiving surface, and expand the blank to gauge, justifying the character-punch with reference to the walls of the cavity in which said compression is effected, and finally driving said character-punch to a predetermined depth in the previously-flattened face of the blank while supported in the die.

3. The hereinbefore-described improvement in the art of forming matrices which consists in containing and hardening the matrix-blank and burnishing the matrix-receiving surface and subsequently driving the matrix impression in said burnished surface as and for the purpose set forth.

4. The hereinbefore-described improvement in the art of forming matrices which consists in subjecting the blank to pressure within an isolated die-cavity to form and harden it, burnishing the matrix-receiving surface while the material is under elastic tension within the die by a movement of one of the die-surfaces, and subsequently forming the drive in said burnished surface.

5. The hereinbefore-described improvement in the art of forming matrices for type-setting machines which consists in first forming a blank longer than the finished matrix and smaller in cross-section; subjecting said blank to longitudinal pressure between insulating walls to compress, harden and shape it; burnishing the surface of the blank; and driving the character-punch into said burnished surface to form the matrix-cavity.

6. The hereinbefore-described improvement in the art of forming matrices which consists in compressing and burnishing the blank and driving the matrix-cavity while the blank is contained and supported in the compression-die.

7. The hereinbefore-described improved step in the art of forming matrices, which consists in burnishing the matrix-surface by a movement imparted to one of the walls or surfaces of the die-cavity in which the compression of the blank is performed.

700,301. DIE MECHANISM FOR MATRICES. ARTHUR W. CATHAM, Philadelphia, Pa., assignor to Lanston Monotype Machine Company, New York, N. Y., a Corporation of Virginia. Filed Jan. 31, 1902. Serial No. 70,802. (No model.)

Claim.—1. In a die mechanism such as described, the combination with a die and a compression-plunger, of a movable planishing-surface forming one wall of the die-cavity, as set forth.

2. In a die mechanism such as described, the combination of a die, a compression-plunger and an opening laterally-movable abutment or slide acting both as a wall of the die-cavity and a planishing medium for the face of the blank, substantially as described.

3. In a die mechanism such as described, the combination with the die and compression-plunger of a movable slide closing one end of the die and an impressing punch or plunger, substantially as described.

4. In a die mechanism such as described, the combination with the plunger and plates of a power-press, of a die supported on the plates and adjustable laterally of the plunger, a compression-plunger fixed to and working in one end of said die, a plate or cover for the opposite end of the die movable transversely of the latter, and a character-punch secured to the press-plunger in line with the die; substantially as described.

5. In a die mechanism such as described, the combination of the perforated die-block, the die located in one end thereof, the tubular support, the compression-plunger, the plunger-supporting sleeve and the disk engaging the rear end of said compression-plunger; substantially as described.

6. In a die mechanism such as described and in combination with the die, its compression-plunger and the opening abutment or plate closing one end of the die, of a plunger-actuating mechanism adapted to effect successive advance movements of the plunger for first compressing and then ejecting the blank; substantially as described.

7. In a die mechanism such as described, the combination of the following elements, to wit: a stationary die; a character-punch in alignment with the opening in said die, a slide movable laterally of the die intermediate the latter and the character-punch, said slide forming one wall of the die-cavity, a compression-plunger movable within the die opposite said slide; and actuating mechanism competent to advance the compression-plunger and reciprocate the slide; substantially as described.

8. In a die mechanism such as described, the combination of the following elements, to wit: a stationary die; a slide closing one end of said die; a compression-plunger in alignment with the opening in the opposite end of the die; and a cam connected through transmitting devices to said compression-plunger, said cam being provided with two gradients of progressively increased prominences separated by a concentric section to produce a dwell between successive advance movements of the plunger; substantially as described.

700,302. RAILWAY BLOCK-SIGNALING SYSTEM. WHITEHEAD H. CHAPMAN, Boston, and WILLIAM FENNER, Lynn, Mass. Filed May 3, 1901. Serial No. 59,573. (No model.)

Claim.—1. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, actuating mechanism for each signal, means at both ends of the block for rendering said mechanism operative to set both signals, locking devices for said signals, actuating mechanism therefor, and means at both ends of the block for rendering said mechanism operative to actuate the locking devices to release the signals, substantially as described.

2. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, actuating mechanism for each signal, means at each end of the block for rendering the actuating mechanism of the signal at the other end operative to set a signal, and means actuated by the setting of one signal for rendering the actuating mechanism of the other signal operative to set a signal, substantially as described.

3. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, an opening-magnet for each signal, means at both ends of the block for rendering said magnets operative to set both signals, locking devices for said signals, actuating mechanism therefor, and means at both ends of the block for rendering said mechanism operative to actuate the locking devices to release the signals, substantially as described.

4. A railway block-signal system, having, in combination, a signal, an opening-magnet therefor, a circuit including said magnet, controlled means for closing said circuit, and a magnet in said circuit for maintaining said circuit closed, substantially as described.

5. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, an opening-magnet for each signal, circuits for said magnets, circuitous in said circuits, actuating means therefor, means at each end of the block for rendering said actuating means operative to close the circuit of the magnet at the other end and means actuated by the setting of one signal for rendering said actuating means operative to close the circuit of the opening-magnet of the other signal, substantially as described.

6. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, an operating-magnet for each signal, means at each end of the block for rendering the magnet at the other end operative to set a signal, and means actuated by the setting of one signal for rendering the magnet of the other signal operative, substantially as described.

7. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, an operating-magnet for each signal, means for closing said circuits, and a locking device for one of the signals acting to control the means for closing the circuit of the magnet of the other signal, substantially as described.

8. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, an operating-magnet for each signal, means at one end of the block for rendering the magnet at the other end operative to set a signal, and a locking device for said signal acting to render the magnet of the other signal operative, substantially as described.

9. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, an operating-magnet for each signal, a single line-wire, circuits for said magnets including said line-wire, means for closing said circuits, and means actuated by the setting of one signal for controlling the means for closing the circuit of the magnet of the other signal, substantially as described.

10. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, actuating mechanism therefor, a locking device for each signal, an electromagnet for actuating each locking device to release a signal, means for closing a circuit including one of said magnets and means controlled by said magnet for closing a circuit including the other magnet, substantially as described.

11. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, actuating mechanism therefor, a single controller acting to control the return of both signals to normal position, means operating independently of the controller for rendering said mechanism operative to set both signals and means rendered operative by one entering and leaving the block for actuating the controller to prevent the return of the signals until the last car leaves the block, substantially as described.

12. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, actuating mechanism therefor, a locking device for each signal, means for actuating said locking device to release the signals, a controller, and means rendered operative by one entering and leaving the block for actuating the controller to prevent the return of said locking device until the last car leaves the block, substantially as described.

13. A railway block-signal system, having, in combination, a signal, actuating mechanism therefor, a locking device for said signal, means for actuating said locking device to release the signal, a controller, means rendered operative by one entering the block for actuating the controller to prevent the return of the signal until the last car leaves the block, and means for actuating the controller when a car enters the block, substantially as described.

14. A railway block-signal system, having, in combination, a signal, actuating mechanism therefor, a locking device for said signal, means for actuating said locking device to release the signal, a controller, means rendered operative by one entering the block for actuating the controller to prevent the return of the signal until the last car leaves the block, and means for actuating the controller when a car enters the block, substantially as described.

15. A railway block-signal system, having, in combination, a signal, means for actuating said signal when a car enters the block, a locking device for said signal, means including a magnet for actuating said locking device to release the signal, a circuit for said magnet, means for closing said circuit at one point when a car leaves the block, a controller acting to open and close said circuit at another point, and means for actuating the controller in a direction to open said circuit when a car enters the block and for actuating the controller in a direction to close said circuit when a car leaves the block, substantially as described.

16. A railway block-signal system, having, in combination, a signal, actuating mechanism therefor, a locking device for said signal, means including a magnet for actuating said locking device to release the signal, a circuit for said magnet, means for closing said circuit, a step-by-step controller, and means for actuating said controller in a direction to maintain said circuit open when a car enters the block and for actuating the controller in a direction to prevent the closing of said circuit when a car leaves the block, substantially as described.

17. A railway block-signal system, having, in combination, a signal movable from normal to a plurality of positions, actuating mechanism therefor and means for determining the position to which the signal is moved by said mechanism, substantially as described.

18. A railway block-signal system, having, in combination, a target rotatable in opposite directions from normal position to display either side, means for rotating the target and means for determining the direction of rotation, substantially as described.

19. A railway block-signal system, having, in combination, a target, a rod for actuating said target provided with right and left spiral grooves, means for moving the rod longitudinally and means for engaging either groove to cause the rod to rotate in either direction, substantially as described.

20. A railway block-signal system, having, in combination, a target, a rod for actuating said target provided with right and left grooves, means for moving the rod longitudinally, means for engaging either groove to cause the rod to rotate in either direction, two loop-circuits and means actuated by the rod to close one circuit when the rod is rotated in one direction and to close the other circuit when the rod is rotated in the opposite direction, substantially as described.

21. A railway block-signal system, having, in combination, a signal, an operating-magnet therefor, a circuit including said magnet, an electromagnet for closing said circuit, means for maintaining said circuit closed, and means actuated by the setting of the signal to break said circuit, substantially as described.

22. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, an operating-magnet for each signal, circuits for said magnets, means for closing said circuits, means at the entering end of the block for rendering said means operative to close the circuit of the magnet at the distant end, means actuated by the setting of the signal at the distant end, and means actuated by the setting of the signal at the entering end to break the circuit of the magnet at the distant end, substantially as described.

23. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, an operating-magnet for each signal, a line-wire, circuits for said magnets including said line-wire, means for closing said circuits, means at each end of the block for controlling the closing of the circuit of the magnet at the other end, and means actuated by the setting of either signal for controlling the closing of the circuit of the magnet of the other signal, substantially as described.

24. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, means for moving each signal from normal to either of two positions, and means at each end of the block for rendering said means operative to move the signals to different positions, substantially as described.

25. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, actuating mechanism therefor, a locking device for each signal, a magnet for actuating each locking device to release the signal, a controller, means rendered operative by one entering the block for actuating the controller to prevent the return of the signal until the last car leaves the block, and means for actuating the controller when a car enters the block, substantially as described.

26. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, actuating mechanism therefor, a locking device for each signal, a magnet for actuating each locking device to release the signal, a controller, means rendered operative by one entering the block for actuating the controller to prevent the return of the signal until the last car leaves the block, and means for actuating the controller when a car enters the block, substantially as described.

27. A railway block-signal system, having, in combination, a signal, actuating mechanism therefor, a controller acting to control the return of the signal to normal position, means rendered operative by one entering and leaving the block for actuating the controller to prevent the return of the signal until the last car leaves the block, and means for actuating the controller when a car enters the block, substantially as described.

28. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, actuating mechanism therefor, a locking device for each signal, means for actuating said locking device to release the signal, a controller, and means rendered operative by one entering and leaving the block for actuating the controller to prevent the return of the signal until the last car leaves the block, and means for actuating the controller when a car enters the block, substantially as described.

29. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, actuating mechanism therefor, a locking device for each signal, means for actuating said locking device to release the signal, a controller at each signal acting to control the return of both of said locking devices, actuating mechanism therefor, and means at both ends of the block for rendering the actuating mechanism of both signals operative to set the signals, and to render the actuating mechanism of one of the controllers operative, and means actuated by the setting of the signals for preventing the return of the other controller, substantially as described.

30. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, actuating mechanism therefor, a locking device for each signal, means for actuating said locking device to release the signal, a controller at each signal acting to control the return of both of said locking devices, actuating mechanism therefor, means at both ends of the block for rendering the actuating mechanism of both signals operative to set the signals, and to render the actuating mechanism of one of the controllers operative, and means actuated by the setting of the signals for preventing the return of the other controller, substantially as described.

31. A railway block-signal system, having, in combination, a signal, actuating mechanism therefor, means for rendering said mechanism operative to set the signal, means for rendering the signal, a controller for said rendering means, and means rendered operative by one entering and leaving the block for actuating the controller to prevent the return of the signal until the last car leaves the block, substantially as described.

32. A railway block-signal system, having, in combination, a signal at each end of a track-section or block, means for successively setting said signals and means for successively restoring said signals, substantially as described.

33. A railway block-signal system, having, in combination, a signal, actuating mechanism therefor, means for rendering said mechanism operative to set the signal, means for rendering the signal, a controller for said rendering means, and means rendered operative by one entering and leaving the block for actuating the controller to prevent the return of the signal until the last car leaves the block, substantially as described.

700,808. VERTICAL GRAIN-SCALE. FRANK E. GLASER, New York, N. Y. Filed Apr. 29, 1898. Serial No. 57,964. (No Model.)

Claim.—1. The combination of a vertically-movable load-receiver, scale-weights connected therewith, a supplemental weight, a catch arranged in the path of the supplemental weight and adapted to support the same, means for tripping the catch, and a tension device consisting of an adjusting-curve pivoted to the catch, and a coiled spring mounted on the adjusting-curve and engaging the same and the catch, substantially as described.

2. The combination of a frame or casing, a vertically-movable load-receiver, scale-weights connected therewith, a supplemental weight, a catch for supporting the supplemental weight, means for tripping the catch, and a tension device consisting of an adjusting-curve mounted in a threaded opening of the frame or casing and loosely passing through the catch, washers mounted on the adjusting-curve and located at opposite sides of the catch, and a spring engaging the curve and the catch, substantially as described.

3. The combination of a vertically-movable load-receiver, a frame or casing, scale-weights connected therewith, a supplemental weight, a catch pivotedly mounted at its upper end on the frame or casing and arranged to support the supplemental weight, an adjusting-curve mounted in a threaded opening of the frame or casing and passing through the catch, a spring disposed on the adjusting-curve and engaging the catch, and means for tripping the catch, substantially as described.

4. In a scale, the combination of a vertically-movable load-receiver, a latch for locking the scale out of operation, a reciprocating operating-bar arranged horizontally and engaging the catch, and means for automatically lifting the bar when the same is reciprocated, whereby the bar will be automatically disengaged from the latch, substantially as described.

5. In a scale, the combination of a vertically-movable load-receiver,

a latch for locking the scale out of operation, said latch being arranged to swing, and provided with a leg, and a bar detachably engaging the leg and arranged to be lifted out of such engagement when the latch swings, substantially as described.

6. In a scale, the combination of a vertically-movable load-receiver, a latch for locking the scale out of operation, said latch being capable of swinging and provided with a leg, and a bar engaging one side of the leg and arranged to be engaged by the opposite side of the leg when the latch swings, whereby the latch will be tripped automatically, substantially as described.

7. In a scale, the combination of a vertically-movable load-receiver, a latch for locking the scale out of operation, said latch being capable of swinging and provided with a leg, and a bar provided with a shoulder engaging one side of the leg, said bar being adapted to be lifted out of such engagement by the leg when the latch swings, substantially as described.

8. In a scale, the combination of a vertically-movable load-receiver, a pivotally-mounted latch for locking the scale out of operation, said latch being provided with a guide and having a transversely-disposed leg arranged at a slight inclination when the latch is in its engaging position, a bar passing through the guide and having a shoulder engaging the upper edge of the leg, and means for yieldingly mounting the bar, substantially as described.

9. In a scale, the combination of a vertically-movable load-receiver, a latch for locking the scale out of operation, said latch being provided with a leg, a bar disposed approximately horizontally and arranged above and engaging the leg, a spring connected with and adapted to return the bar, and means for limiting the movement of the same, substantially as described.

10. The combination of a vertically-movable load-receiver, a fixed bracket or support arranged above the same, movable cut-off located at opposite sides of the bracket or support and provided with weighted arms adapted to close the cut-off automatically, latches for holding the cut-off open, and means carried by the load-receiver for tripping the latches and for lifting the arms to open the cut-off, substantially as described.

11. The combination with a vertically-movable load-receiver, of a chute or hopper located above the load-receiver, the substantially V-shaped bracket or support 101 mounted within the chute or hopper, the cut-off hingedly mounted within the chute or hopper at opposite sides of the bracket or support and provided with means for automatically closing them, latches for holding the cut-off open, and tripping devices carried by the load-receiver for engaging the latches, substantially as described.

12. The combination of a vertically-movable lead-receiver, a supply chute or hopper having a contracted or tapered lower portion, the V-shaped breaker or support arranged within the supply chute or hopper and spaced from the breaker or support, cut-off mounted at opposite sides of the latter, and means operated by the lead-receiver for opening and closing the cut-off, substantially as described.

13. The combination of a vertically-movable lead-receiver, a supply chute or hopper having oppositely-inclined lower portions, the inclined deflector arranged within the supply chute or hopper, the V-shaped breaker mounted within the chute or hopper and spaced from the inclined lower portions of the same to provide opposite passages, cut-off hinged at the lower edges of the inclined deflector, and means operated by the lead-receiver for opening and closing the cut-off, substantially as described.

14. The combination of a vertically-movable lead-receiver, a cut-off, a latch arranged to hold the cut-off open and provided with an arm or lever having an inclined edge, and provided above the same with a recess, and a tripping device arranged to engage the inclined edge, substantially as and for the purpose described.

15. The combination of a vertically-movable lead-receiver, a cut-off having a weighted arm, a latch pivoted at its upper end and arranged to hold the weighted arm in an elevated position, a lever or arm connected with and spaced from the catch and provided with an inclined edge, and a tripping device carried by the lead-receiver and arranged to engage the inclined edge, substantially as described.

16. The combination of a vertically-movable lead-receiver, a supply chute or hopper, cut-off mounted within the chute or hopper and provided with weighted arms, the latch pivoted at opposite sides of the chute or hopper and arranged to hold the arms elevated and provided with depending arms or levers, the tripping devices carried by the lead-receiver and arranged to engage the arms or levers, and the lifting device carried by the said lead-receiver and arranged to engage the weighted arms of the cut-off, substantially as described.

17. The combination of a vertically-movable lead-receiver provided at the top with an entrance-opening, a valve pivoted to the lead-receiver and arranged to swing inward and outward to vary the size of the entrance-opening, the pivoted cut-off mounted on the lead-receiver and arranged on the exterior of the valve and adapted to swing inward and outward over the same, and means arranged to be engaged by the cut-off for opening and closing the same, substantially as described.

18. The combination of a vertically-movable lead-receiver provided at the top with an entrance-opening, an adjustable valve or cut-off pivotedly mounted and arranged to vary the size of the said opening, a ratchet-wheel connected with the valve or cut-off, a pawl for locking the ratchet-wheel against movement in either direction, and an automatically-operating cut-off for covering the opening when the lead-receiver moves downward, substantially as described.

19. The combination of a vertically-movable lead-receiver provided at the top with an entrance-opening, the automatically-operating oscillatory valve arranged to swing inward and outward to cover and uncover the said opening, and provided with an arm, and means arranged to be engaged by the arm for opening and closing the cut-off when the lead-receiver moves upward and downward, substantially as described.

20. The combination of a vertically-movable lead-receiver provided with an entrance-opening, a hinged valve mounted on the lead-receiver and arranged to swing inward and outward to cover and uncover the said entrance-opening, said valve being provided with an arm rigid with it, and fixed stops arranged in the path of the arm and located above and below the same, whereby the valve is automatically opened and closed when the lead-receiver moves upward and downward, substantially as described.

21. The combination of a vertically-movable lead-receiver provided with an entrance-opening, a movable cut-off mounted on and carried by the lead-receiver and provided with an arm, and steps arranged to be engaged by the arm when the lead-receiver moves upward and downward, one of the steps being disposed vertically and forming a track for holding the cut-off in its closed position, substantially as described.

22. The combination of a vertically-movable lead-receiver provided at its top with opposite openings, oscillating cut-off arranged to cover and uncover the said openings and provided with arms, steps arranged to engage the arms to open the cut-off, and vertical tracks arranged to engage the arms and close the cut-off, and maintain the same in such position during the major portion of the vertical movement of the lead-receiver, substantially as described.

23. The combination of a vertically-movable lead-receiver provided at its top with opposite openings, oscillating cut-off provided with arms, a plate or frame having vertical flanges forming tracks and arranged to be engaged by the arms, and adjustable stops mounted on the plate or frame and arranged to engage the arms, substantially as described.

24. The combination of a vertically-movable lead-receiver, a tapered

chute provided with a spreader, a neck located below the spreader and extending beyond the same to form opposite openings, the oscillating cut-off mounted beyond the neck and arranged to cover and uncover the said openings, and means for actuating the cut-off, substantially as described.

25. The combination of a vertically-movable lead-receiver, a tapered chute mounted within the same, a spreader arranged at the bottom of the chute, a neck spaced from the chute to form trays and extended beyond the spreader, the adjustable cut-off or valve arranged to extend inward over the neck, and the automatically-operating cut-off arranged to close the openings at the top of the neck, substantially as described.

700,804. CORNERED RULE AND SQUARE. FRANK J. COOPER, Columbia Falls, Me. Filed July 20, 1901. Serial No. 70,111. (No model.)

Claim.—The combination with an ordinary two-foot rule having on the outer end of one of its hinged members a head with a notched head, and shoulders on opposite sides of the head formed at the intersection of said head and said rule, the shoulders being partly vertical and partly curved, and an outer member of the rule having at its inner portion a recess a spring-latch with a bolt mounted in the recess, of an indicator consisting of two plates with curved inner ends secured to the inner end of the outer member of the rule, a rectangular opening in one of the plates for the passage of a projection of the latch to operate the latch so that the bolt thereof will coast with the notches of the head of the rule, and the inner curved ends of the plates of the indicator pivoted on opposite sides of the head of the rule whereby said vertical and curved shoulders formed at the intersection of the head and its head coast with the curved ends of the plates and the inner vertical edge thereof, substantially as specified.

700,805. MACHINE FOR FIXING SPANGLER MATERIAL TO TEXTILE FABRIC. ROBERT CURRIE, Paris, France. Filed Nov. 7, 1901. Serial No. 81,000. (No model.)

Claim.—1. In a sewing or embroidering machine for attaching spangled material to fabric, the combination with stitch-forming mechanism

for a passage or conduit through which the spangled material passes to the fabric, said conduit being of elongated cross-section to prevent the spangled material from becoming twisted and to present the same in proper position for the binding-thread to pass between the spangles, and a thread-carrier passing a binding-thread around the spangled material between the spangles and around the stitches formed by the stitch-forming mechanism.

2. In a sewing or embroidering machine for attaching spangled material to fabric, the combination with a hollow needle-bar through which the spangled material is adapted to pass, a needle carried thereby and co-operating stitch-forming mechanism, of a hollow nipple below the needle-bar through which the spangled material passes from the needle-bar to the fabric, the passage through the needle-bar and nipple being of elongated cross-section to prevent the spangled material from becoming twisted and to present the same in proper position for the binding-thread to pass between the spangles, and a thread-carrier passing a binding-thread around the spangled material between the spangles and around the stitches formed by the stitch-forming mechanism.

3. In a sewing or embroidering machine for attaching spangled material to fabric, the combination with a hollow needle-bar, a needle carried thereby and co-operating stitch-forming mechanism, of a reel above said bar on which the spangled material is wound, a roller or pulley over which the spangled material passes to the passage through the needle-bar which is of elongated cross-section to prevent the spangled material from becoming twisted, and a thread-carrier passing a binding-thread around the spangled material between the spangles and around the stitches formed by the stitch-forming mechanism.

700,806. COIN-DELIVERY MACHINE. ADAM M. GASTNER, Philadelphia, Pa. Filed Aug. 28, 1901. Serial No. 72,000. (No model.)

Claim.—In a coin-delivery machine on attachment to the coin-chute consisting of a triangular piece of metal having its one side flat and its other side thickest in its center and sloping to its edges and fastened to said chute directly above the mouth of said chute, substantially as described and shown.

700,807. CARBURIZER. GEORGE C. DEHN and JEREMIAH A. RAHMER, Butler, Ind. Filed Feb. 15, 1901. Serial No. 47,672. (No model.)

Claim.—1. In a gasless-gas generator, the combination of a generator, a feed-pipe leading therefrom, a carbide-burner in operative relation

tion to said generator, a shield over the latter, and a service-pipe having its lower end disposed opposite the discharge of the generator and above said shield, substantially as described.

2. The combination of a generator, a reservoir for gasoline, a feed-pipe leading from said reservoir to said generator, a carbide-burner disposed under the generator, a shield above the latter and through which the vapor discharge of the generator passes, and a service-pipe having its lower end disposed above said shield opposite and above said vapor discharge of said generator, said service-pipe passing through the body of gasoline in the said reservoir, substantially as described.

700,808. CONVEYER-BELT. JAMES H. DODGE, Philadelphia, Pa., assignor to the Link Belt Engineering Company, Philadelphia, Pa., a Corporation of Pennsylvania. Filed Aug. 27, 1901. Serial No. 72,000. (No model.)

Claim.—1. A conveyor-belt made of two or more independent endless sections arranged side by side, the abutting edges of the said sections being hinged together, substantially as described.

2. A conveyor-belt made of two or more independent endless sections arranged side by side, the abutting edges of the said sections being hinged together by a flexible hinge so that it will pass around the head wheels of the conveyor, substantially as described.

3. A conveyor-belt made of a central endless section and two side endless sections, said sections being flexible and the abutting edges of said sections being hinged together, substantially as described.

700,809. PISTON FOR GAS OR OTHER MOTORS. HERMAN E. BORN, Furberg, Germany, assignor to The Firm of Vereinigte Maschinenfabrik Augsburg und Maschinenbaugesellschaft Nürnberg, A.-G., Furberg, Germany. Filed Dec. 15, 1900. Serial No. 700,000. (No model.)

Claim.—1. In combination, the cross-head, the semi-cylindrical removable and interchangeable guiding portions carried thereby, a short shaft integral with said cross-head extending axially rearward therefrom, a rear piston portion threaded on said shaft and packing-rings carried thereby, substantially as described.

2. In combination, a cross-head, a guiding and a packing cylinder, said guiding-cylinder consisting of a plurality of segmental sections removably secured to the cross-head and a connection between the packing-cylinder and the cross-head, substantially as described.

700,810. ALTERNATING-CURRENT ELECTRIC MOTOR AND CONTROLLING MEANS THEREFOR. RUDOLF ROHMERT, Yonkers, N. Y.; Rudolf Rohmeyer, Jr., Carl Rohmeyer, and Mary T. Rohmeyer executors of said Rudolf Rohmeyer, deceased. Filed Aug. 15, 1901. Serial No. 68,722. (No model.)

Claim.—1. In an alternating-current motor, provided with multipole magnetic field-circuit; an armature provided with coils connected in series in a closed circuit, and occupying recesses in the periphery of the armature-core; counterbalancing field-coils of high resistance within the influence of the magnetic field-circuit, said counter field-coils comprising short-circuited windings surrounding the said field-circuit, closely adjacent to and overlying portions of the counter-coils.

2. The combination with an alternating-current motor provided with

a suitable commutator and appropriate brushes relatively mounted on the armature-shaft, of a circuit-breaker and controlling mechanism for said brushes and circuit-breaker, accessible to the operator, the motor organization being such that when the motor is at full speed, the operator by relatively moving the brushes toward their insipidative position will deprive the motor of its driving power by increasing the self-induction of the motor, the circuit-breaker opening for cutting off the current from the motor when said self-induction reaches its maximum.

3. The combination with an alternating-current motor, provided with relatively-mounted brushes, adapted by variations in position to start, stop, and reverse the motor, of a circuit-breaker, a set of counter field-coils interposed between similarly-magnetized cheeks and located closely adjacent to the armature, and controlling mechanism accessible to the operator for relatively varying the position of the brushes, as for stopping and reversing, and also for reversing the current in the counter field-coils by variation in the position of the circuit-breaker.

4. In an alternating-current electric motor, the combination of a motor-armature, and a multipolar electromagnet embodying a series of iron cheeks in several pairs, each pair of which is embraced by a short-circuited coil.

5. In an alternating-current electric motor, the combination with a suitable armature, of a multipolar field-magnet, constructed in separable sections, each containing different magnets which are provided with counter field-coils for preventing self-induction of the armature.

6. In an alternating-current electric motor, the combination with a suitable armature, of a multipolar electromagnet embodying separated masses of laminated iron, each mass composed, longitudinally recessed, and parallel with the others, and separate rectangular field-coils, each of which at its sides comprise recesses in two separated adjacent masses of field-iron, and serves as the exciting medium for two separated magnets.

7. In combination, an alternating-current motor having an armature provided with a commutator, a tilting cut-out or switch for said motor, a controlling-shaft accessible to the operator, commutator-brushes relatively operated for starting, stopping, and reversing; the cut-out or switch, intermediate shunting and gearing relatively coupling the controlling-shaft to the brushes, and a cam-lever coupled to the tilting cut-out, and caused by said shunting to vibrate with appropriate lost motion, as between the rotation of the controlling-shaft and the operation of the cut-out.

700,811. TREATMENT OF COMPLEX AND REFRACTORY ORES. FRANK HALLERMAN, London, England, assignor to the Hallerman Reduction, (New Process) Limited, London, England. Filed Feb. 18, 1906. Serial No. 5,315. (No model.)

Claim.—1. The process of treating complex and refractory ores containing lead, silver and zinc, which consists in smelting the raw ores, positively drawing off the fumes and gases, and charging them with water to condense and mix them therewith, cutting out the lead, silver and part of the zinc compounds from the resulting liquor, as a dudge, separating and drying the dudge, fusing the dudge with impure caustic alkali containing sulfide, thereby precipitating the lead in metallic form, separating the lead, treating the residual molten mass to recover zinc, and treating the liquor from which the dudge was separated with said caustic soda, thereby precipitating zinc, and converting the caustic soda into sodium carbonate, and recovering the sodium carbonate, substantially as described.

2. The process of treating complex and refractory ores containing lead, silver and zinc, which consists in smelting the raw ores, drawing off the fumes and gases and charging them with water to condense and mix them therewith, cutting out the lead, silver and part of the zinc compounds from the resulting liquor, as a dudge, separating and drying the dudge, fusing the dudge with impure caustic alkali containing sulfide, thereby precipitating the lead in metallic form, separating the lead, treating the residual molten mass to recover zinc, and treating the liquor from which the dudge was separated to recover zinc, and treating the liquor from which the dudge was separated with said caustic soda, thereby precipitating zinc, and converting the caustic soda into sodium carbonate, and recovering the sodium carbonate, substantially as described.

3. The process of treating complex and refractory ores containing lead, silver and zinc, which consists in smelting the raw ores, drawing off the fumes and gases and charging them with water to condense and mix them therewith, cutting out the lead, silver and part of the zinc compounds from the resulting liquor, as a dudge, separating and drying the dudge, fusing the dudge with impure caustic alkali containing sulfide, thereby precipitating the lead in metallic form, separating the lead, treating the residual molten mass to recover zinc, and treating the liquor from which the dudge was separated with said caustic soda, thereby precipitating zinc, and converting the caustic soda into sodium carbonate, and recovering the sodium carbonate, substantially as described.

4. The process of treating complex and refractory ores containing lead, silver and zinc, which consists in smelting the raw ores, drawing off the fumes and gases and charging them with water to condense and mix them therewith, cutting out the lead, silver and part of the zinc compounds from the resulting liquor, as a dudge, separating and drying the dudge, fusing the dudge with impure caustic alkali containing sulfide, thereby precipitating the lead in metallic form, separating the lead, treating the residual molten mass to recover zinc, and treating the liquor from which the dudge was separated with said caustic soda, thereby precipitating zinc, and converting the caustic soda into sodium carbonate, and recovering the sodium carbonate, substantially as described.

5. The process of treating complex and refractory ores containing lead, silver and zinc, which consists in smelting the raw ores, drawing off the fumes and gases and charging them with water to condense and mix them therewith, cutting out the lead, silver and part of the zinc compounds from the resulting liquor, as a dudge, separating and drying the dudge, fusing the dudge with impure caustic alkali containing sulfide, thereby precipitating the lead in metallic form, separating the lead, treating the residual molten mass to recover zinc, and treating the liquor from which the dudge was separated with said caustic soda, thereby precipitating zinc, and converting the caustic soda into sodium carbonate, and recovering the sodium carbonate, substantially as described.

6. The process of treating complex and refractory ores containing lead, silver and zinc, which consists in smelting the raw ores, drawing off the fumes and gases and charging them with water to condense and mix them therewith, cutting out the lead, silver and part of the zinc compounds from the resulting liquor, as a dudge, separating and drying the dudge, fusing the dudge with impure caustic alkali containing sulfide, thereby precipitating the lead in metallic form, separating the lead, treating the residual molten mass to recover zinc, and treating the liquor from which the dudge was separated with said caustic soda, thereby precipitating zinc, and converting the caustic soda into sodium carbonate, and recovering the sodium carbonate, substantially as described.

7. The process of treating complex and refractory ores containing lead, silver and zinc, which consists in smelting the raw ores, drawing off the fumes and gases and charging them with water to condense and mix them therewith, cutting out the lead, silver and part of the zinc compounds from the resulting liquor, as a dudge, separating and drying the dudge, fusing the dudge with impure caustic alkali containing sulfide, thereby precipitating the lead in metallic form, separating the lead, treating the residual molten mass to recover zinc, and treating the liquor from which the dudge was separated with said caustic soda, thereby precipitating zinc, and converting the caustic soda into sodium carbonate, and recovering the sodium carbonate, substantially as described.

700,812. NON-REFILLABLE BOTTLE. BARNES A. FARMER and HERMAN R. KERN, Astoria, Ala. Filed Aug. 21, 1906. Serial No. 11,302. (No model.)

Claim.—1. The combination with a bottle, of a cylindrical case arranged in the neck thereof, a valve seated in the cylindrical case, a stopper also arranged in the said cylindrical case and projecting above same, the upper portion of said stopper having an opening adjacent to the top, the lower portion of the stopper having a tube arranged therein, a plug

located in the tube, and the wire connected to the plug and passing out through the opening adjacent to the top of the stopper, substantially as described.

2. The combination with a bottle, of a cylindrical case arranged in the neck thereof, a valve seated within the case, a stopper located also within the case and projecting above the case, said stopper having a tube adapted to receive the upper end of the valve-stem, a plug located in said tube and having a wire connected thereto, said wire passing out through an opening arranged adjacent to the top of the stopper, the upper portion of the stopper having a series of inclined ledges arranged upon the exterior thereof, and a cap fitted upon the neck of the bottle and having the depending flange adapted to be embedded in cement contained between the neck of the bottle and the cylindrical case, substantially as and for the purpose described.

700,813. CORE FOR CASTING GEAR-WHEELS. LUTHER E. FAWCETT, Philadelphia, Pa.; Harry J. Fawcett, administrator of said Luther E. Fawcett, deceased. Filed Oct. 2, 1901. Serial No. 77,598. (No model.)

Claim.—1. The combination of a core having a central body or stem, an annular rim, a transverse web connecting the body with the rim, at or near one end of the latter, and lateral ribs connecting the rim, at or near its opposite end, with the body, a key-block seated in the web of the core, supports for maintaining the core and key-block in normal form and location, and said ribs and lateral ribs formed in the core.

2. The combination of a core having a central body or stem, a transverse web, and a print at one end, a center support fitted in and projecting from the body of the core at the end opposite the print, a stop or bearing in which said center support is fitted, and a key-block seated in the web of the core.

3. The combination of a core having a central body or stem and a transverse web, a key-block seated in the web of the core and having internal spaces or passages, a center support fitted in and projecting from the body of the core, and a stop-core fitted in the web of the core and in one of the passages of the key-block.

4. The combination of a core having a central body or stem and a transverse web, a key-block seated in the web of the core and having internal spaces or passages, a main vent extending throughout the major portion of the length of the body of the core, and a lateral vent formed in the web of the core and connecting one of the internal spaces of the key-block with the main vent.

5. The combination of a core having a central body or stem and a transverse web, a key-block seated in the web of the core, and a strip of refractory material, an asbestos paper or the like, fitted in the core adjacent to the key-block.

6. The combination of a core having a central body or stem and a transverse web, a key-block seated in the web of the core, a main vent extending throughout the major portion of the length of the body of the core, and a lateral vent formed in the web of the core and leading from the main vent.

700,814. STEAM-TURBINE. JOHN S. FARMER, New York, N. Y. Filed Jan. 21, 1908. Serial No. 62,080. (No model.)

Claim.—1. In combination with a water or steam turbine, the main and exhaust-grooves alternating and placed opposite each other around the periphery on each side of a turbine wheel.

2. The combination with a water or steam turbine, the main and exhaust-grooves alternating and placed opposite each other on both sides of turbine wheel or wheels.

3. In combination with a water or steam turbine one or more turbine wheels having buckets extending radially and parallel on each side adapted to discharge into the same bucket or set of buckets.

4. In combination with a water or steam turbine, the main and exhaust-grooves alternating and placed opposite each other around the periphery on each side of a turbine wheel, the main adjusted to direct energy against parts of turbine wheel in such a manner that when the wheel is at a standstill the energy discharged will act independently against the wheel and exhaust but when the wheel is turning at a given speed the energy discharged from opposite main will collide and act componently against the wheel, substantially as described and for the purpose set forth.

5. In combination with a water or steam turbine the casing, one or more turbine wheels with buckets fitted steam-tight therein, ridges of main and exhaust-grooves alternating and placed opposite each other on both sides of turbine wheel or wheels in such a manner that the kinetic energy emitted from opposite main will collide when wheel is turning but will exhaust when wheel is at a standstill as described and set forth in the foregoing specification.

700,815. GRAIN-DRILL. WILLIAM FRYER, Middletown, Ohio. Filed Mar. 14, 1908. Serial No. 64,338. (No model.)

Claim.—1. In a grain-drill, the combination of the feed-shaft, the main axle, and changeable-speed gearing intermediate between the shaft and axle, the axle being divided or formed in two sections, and the gearing being duplicated for each section.

2. In a grain-drill, the combination of the feed-shaft, the main axle, the latter being divided into two separate sections, a, a', a driving-gear on each section, a gear on the feed-shaft, and an adjustable gear connection between each driving-gear, and the corresponding gear on the feed-shaft.

3. In a grain-drill, the combination of the feed-shaft, the main axle, the latter being divided into two separate sections, a, a', a driving-gear g on each section, pinions b, b' on the feed-shaft, one for each gear g, and counter-shafts c, c, connecting the driving-gears g with the pinions on the feed-shaft, the counter-shafts having adjustable pinions i adapted to be adjusted on or to mesh with different rows of teeth on the gears g.

700,816. BALL-COOK. FRED F. PLANN, Worcester, Mass. Filed Apr. 22, 1891. Serial No. 64,186. (No model.)

Claim.—1. In a flushing-tank, the combination of a valve, a float in connection with the valve, a spring, at one end in operative connection with the float and at the other end in engagement with an adjustable abutment, means connecting with the abutment whereby the spring is progressively compressed during the rise of water in the tank substantially as set forth.

2. In a flushing-tank, the combination of a valve, a float in connection with the valve, resilient means to submerge the float for a predetermined interval in opposition to the buoyant force of the rising water, an adjustable abutment connecting with said resilient means, a rider operatively connected with the abutment and the valve to contract the said resilient means as and for the purpose set forth.

3. In a flushing-tank, the combination of a valve, a float and float in connection therewith, a spring operatively surrounding said float, an adjustable and movable abutment in contact with one end of the spring, means whereby the abutment is actuated to contract said spring as and for the purpose set forth.

4. In a flushing-tank, the combination of a valve, a float and float in connection therewith, a spring surrounding said float and in operative connection therewith, to submerge said float against the buoyant force of the flowing water, an adjustable and movable mechanism loosely held upon the float and cooperating with the valve and spring to contract said spring and then submerge the float substantially as set forth.

5. In a flushing-tank, the combination with a valve-stem of an elastic gland, a loose washer, provided with arms, bearing against said gland, operating means for said valve-stem, one or more lugs secured to said valve-stem-opening means, and bearing against said washer-arms to expand said gland substantially as described.

700,817. CORSET. LOUISA S. FOWLER, Chicago, Ill. assignor to the H. W. Gannard Company, Chicago, Ill. Filed Oct. 24, 1891. Serial No. 64,179. (No model.)

Claim.—1. A corset comprising a body, four fastening-strips of stiff resilient material arranged so as to be substantially parallel, the outer pair being permanently connected with the body, the inner pair being provided with means for detachably connecting their adjacent edges, each of the inner pair having rigidly secured along its outer edge a series of projecting eyes, each of the outer pair having rigidly secured along its inner edge a corresponding series of projecting eyes, and lacing for adjust-

ably connecting the eyes of each of the inner strips with the eyes of the adjacent outer strip; said eyes on each consisting of a loop 6 lying substantially in the plane of the fastening-strip to which same is secured, but being twisted from each plane to give a free lead to said lacing, substantially as shown.

2. A corset comprising a body, a pair of flat fastening-strips of stiff resilient material each secured to an adjacent part of the garment, each of said strips having rigidly secured to the edge adjacent to the other strip a series of projecting eyes, and suitable lacing connecting the eyes on one strip with those on the other; said eyes on each consisting of a loop 6 lying substantially in the plane of the fastening-strip to which same is secured, but being twisted from each plane to give a free lead to said lacing, substantially as shown.

3. The corset-fastening comprising a fastened strip of stiff resilient material having a series of projecting eyes rigidly secured to one edge, said eyes each consisting of a wire loop, rounded in cross-section, having its ends fastened on opposite faces of the strip and secured together through said strip, said loop lying substantially in the plane of said strip, but being twisted from each plane, to give a free lead to a lacing, substantially as shown.

700,818. PUMPING-VEHICLE. ALBERT FOWLE, Alexandria, Ind. assignor of one-half to Harvey A. Moore, Indianapolis, Ind. Filed Oct. 18, 1891. Serial No. 73,094. (No model.)

Claim.—1. In a dumping-vehicle, the combination with the body, of a swinging section forming a portion of the bottom thereof, a lever pivoted between its ends to the free end of one of said sections, a link pivoted upon the body and having pivotal connection with one end of said lever, and means for swinging said lever.

2. In a dumping-vehicle, the combination with the body, of a plurality of swinging sections forming the bottom thereof, a plurality of levers each pivoted between its ends to the free end of one of said sections, a plurality of links pivoted upon the body and each pivotally connected to one end of a lever, a bar connecting the opposite ends of all the levers, and means for shifting said bar.

3. In a dumping-vehicle, the combination with the body, of a plurality of swinging sections forming the bottom thereof, a plurality of levers each pivoted between its ends to the free end of one of said sections, a plurality of links pivoted upon the body and each pivotally connected to one end of a lever, a bar connecting the opposite ends of all the levers, a seat pivoted upon the body, a connection between said seat and the bar, and means for holding said seat in its normal position.

4. In a dumping-vehicle, the combination with the body, of a plurality of swinging sections forming the bottom thereof, a plurality of levers each pivoted between its ends to the free end of one of said sections, a plurality of links pivoted upon the body and each having a pivotal connection with one end of an adjacent lever, and means for swinging said levers simultaneously, the arrangement being such that when the sections are thrown into alignment the pivotal point of a link, its point of connection with its lever, and the point of connection of said lever with its section will lie in a substantially straight line.

5. In a dumping-vehicle, the combination with the body, of a plurality of swinging sections forming the bottom thereof, a plurality of levers each pivoted between its ends to the free end of one of said sections, a plurality of links pivoted upon the body and having a pivotal connection with one end of the adjacent lever, the arrangement being such that when the sections are thrown into alignment the pivotal point of the link, its point of connection with its lever, and the point of connection of said lever with its section will lie in a substantially straight line, a bar connecting the opposite ends of all of the levers, a seat pivoted upon the body, and a link connecting said seat and bar, substantially as and for the purpose set forth.

6. In a dumping-vehicle, the combination with the body, of a plurality of swinging sections forming the bottom thereof, a plurality of levers each pivoted to the free end of one of said sections, a plurality of links pivoted upon the body and each having a pivotal connection with an adjacent lever, and means for swinging the said levers simultaneously, the arrangement being such that when the sections are thrown into alignment the pivotal point of each link, its point of connection with its lever, and the point of connection of said lever with its section will lie in a substantially straight line.

7. In a dumping-vehicle, the combination with the body, of a swinging section forming a portion of the bottom thereof, a lever pivoted to the free end of said section, and a link pivoted upon the body and having a pivotal connection with said lever, the arrangement being such that when the swinging section is in normal position the pivotal point of the link, its point of connection with the lever, and the point of connection of said lever with the section will lie in a substantially straight line.

700,819. APPARATUS FOR MOVING HEAVY BODIES. CHARLES V. FOWLER, Los Angeles, Cal. Filed June 17, 1891. Serial No. 64,187. (No model.)

Claim.—1. The apparatus or device for moving heavy bodies consisting of a drum or cylinder of much larger diameter than the reel of the apparatus, the rope wound partly upon the drum and partly upon the reel, the two ropes, one of the ends of each of which is fastened to the reel-drum, and the other end of which ropes is fastened to the axle of the drum, the handle-hoist carried upon the axle of the drum or which the weight or heavy body to be lifted is attached, all operating together in the manner and for the purpose substantially as hereinbefore described.

2. The combination of the drum, the reel, the handle for rotating the reel, the prolonged axle of the drum, the rope connecting the prolonged axle of the drum to the flange of the reel, the handle-hoist carried by or upon the axle of the drum, also the carrier or idler wheel for supporting the drum and its mechanism, all operating together in the manner and for the purpose substantially as set forth.

3. The combination of the drum, the reel, the handle for rotating the reel, the prolonged axle of the drum, the rope connecting the prolonged axle of the drum to the flange of the reel, the handle-hoist carried by or upon the axle of the drum, also the carrier or idler wheel for supporting the drum and its mechanism, all operating together in the manner and for the purpose substantially as set forth.

4. The apparatus or device suspended vertically from the frame carrying the winding-reel, consisting of the drum, the rope wound partly upon the drum and partly upon the winding-reel connecting the drum and winding-reel together, and the two ropes whose upper ends are attached to the flange of the apparatus, with their lower ends attached to the prolonged axle of the drum; also the handle-hoist carried upon the prolonged axle of the drum, all operating together in the manner and for the purpose substantially as set forth.

700,820. WHEAT-GRINDER FOR LOCOMOTIVE ENGINES. CHARLES E. FOX, Chesham, N.H. Filed July 12, 1891. Serial No. 64,171. (No model.)

Claim.—1. In combination with a steam-boller, a plurality of vertical or inclined tube units placed within the combustion-chamber and

each including two parallel headers at the top and two parallel headers at the bottom, said headers united by a plurality of tubes, and the upper portions of said tubes and the upper headers being above the normal water-level, and the lower headers communicating with the water-space and the upper headers communicating with the steam-space of the boiler.

2. In a steam-boller of ordinary locomotive type, the combination, with the fire-box of an inclined crown-sheet extending above the normal water-line, and a series of vertical or inclined water-tubes placed within the fire box the lower ends of the tubes in communication with the water-jacket of the fire-box and the upper terminals of same arranged to discharge upon and down the crown-sheet for the purpose of protecting same from the action of heat, substantially as set forth.

3. In a steam-boller of the ordinary locomotive type, the combination of an inclined crown-sheet extending above the normal water-level with transverse and longitudinal dam-plates erected thereon and preferably forming a part of the heating throat, for the purpose of entrapping thereon a portion of the water discharged upon the upper end of the crown-sheet and flowing down over the same, substantially as set forth.

4. In a steam-boller of the locomotive type, the combination of a fire-box, a series of vertical or inclined water-tubes heated therein, a manifold between the mid series of water-tubes and the rear tube-sheet, and a pocket or funnel-shaped receptacle forming a pendant extension of the manifold for receiving clinker or unburned particles of the fuel, and suitable gate or cut-off arrangement for discharging the contents thereof at pleasure, substantially as set forth.

5. In a steam-boller of the ordinary locomotive type, a fire-box including converging cheeks above and below, forming an inclining shell of irregular shape, said fire-box having its upper side provided for the purpose of inserting and removing a system of vertical or inclined water-tubes attached as part of the steam-generating apparatus, substantially as set forth.

6. In a steam-boller of the modified type hereinbefore described, the combination of a water and steam jacketed fire-box, a series of inclined water-tubes accessible at the top, through an opening piercing the boiler, a removable cover-plate over said opening, a system of water-tubes extending above and below the normal water-line and communicating with the steam and water spaces of the boiler respectively, a haffle-plate for deflecting the extended water carried thereby upward into the steam-space, a cylindrical forward extension containing the upper ends of the tubes and joined to the front lag of the fire-box, a manifold provided at the lower part of the shell near its junction with the fire-box, smaller openings or hand-holes in the lag of the boiler for giving access to the interior of the tube-sections constructed and arranged as and for the purpose hereinbefore set forth.

7. In a fire-box boiler of the type indicated, a fire-box provided with a system of independent laterally-adjustable tube units each consisting of upper and lower "headers" connected by a series of parallel tubes in the common axial plane of the headers, each upper header connected at one end with the steam-space and each lower header being connected at the relatively opposite end with the water-space, in combination with a forward extension of the boiler provided with submerged flues communicating with the combustion-chamber of the fire-box, substantially as set forth.

8. In a fire-box boiler of the type indicated, a fire-box provided with a system of laterally-adjustable tube units inclined forward and connecting above and below in the steam and water spaces of the fire-box, and a series of refractory plates or tiles carried between and upon the lower headers of the tube units, constituting with said headers a haffle-plate to carry the latent products of combustion backward and thence upward around the rear ends of the headers, and thence forward across and between the tubes to the smoke-flues of the forward cylindrical extension of the boiler, substantially as set forth.

700,821. CONVERTING APPARATUS. FREDERICK E. PRINCE, San Francisco, Cal. Filed Sept. 4, 1891. Serial No. 74,394. (No model.)

Claim.—1. The combination is a conveying apparatus of parallel pairs of supporting-cables, supports over which said cables pass, winding-drum around which the cables are movable, trolleys suspended and movable upon the cables, other cables passing around sheaves in said trolleys and a burden-carrier suspended by said cables between the parallel cables, and means by which said burden-carrier may be moved transversely between the parallel cables.

2. The combination is a conveying apparatus of pairs of parallel cables, supports over which said cables pass, trolleys suspended and movable upon the cables, mechanism by which said cables are moved to cause the trolleys to travel outwardly or inwardly in unison, a burden-carrier, supplemental cables from which the carrier is suspended between the parallel cables, and means for extending the supplemental cables to move the carrier transversely between the parallel cables.

3. The combination is a conveying apparatus of two sets of parallel

lateral inboard and outboard cables, trolleys with which said cables are connected from opposite sides whereby said trolleys are movable in unison, a burden-carrier and supplemental cables by which it is suspended between the parallel cables, guide-sheaves upon the trolleys and upon the fixed supports, and winding-drums by which the supplemental cables are actuated to move the burden transversely, or to raise or lower it.

4. The combination in a conveying apparatus of two pairs of parallel inboard and outboard cables, with division-pulleys over which they pass, trolleys movable one upon each of said parallel cables, and with opposite sides of which the ends of the cables are connected whereby the trolleys are moved in unison, and a burden-carrier and supplemental cables by which it is suspended between the trolley-carriers, and means by which the cables are actuated to raise or lower the burden or to move it transversely between the parallel cables.

5. The combination with pairs of parallel cables and their actuating mechanism, and trolleys suspended and movable upon the cables, of supplemental cables connected to the trolleys, a burden-carrier connected to the latter cables, and means for actuating the supplemental cables to cause the burden-carrier to be moved transversely between the parallel cables.

6. The combination in a conveying apparatus of two sets of parallel inboard and outboard cables, winding-drums by which the cables are driven and the trolleys moved in unison in either direction, supplemental winding-drums and supplemental cables connected and movable thereby, guide-sheaves upon the towers and the trolleys, and a burden-carrier connected to the supplemental cables and located between the main cables, and capable of being moved transversely thereby between the parallel cables.

7. The combination in a conveying apparatus of two sets of inboard and outboard cables and winding-drums operable in unison to move the cables, trolleys to which the cables are connected at opposite sides, and supplemental cables passing over sheaves in each of the trolleys, a burden-carrier suspended from the supplemental cables, winding-drums, guide-sheaves, and connections whereby the "fall" is operated without a standing cable.

8. The combination in a conveying apparatus of parallel traveling cables, trolleys connected and movable in unison therewith, a pair of cables passing over sheaves in the trolleys, and thence extending inward toward each other, a burden-carrier suspended from the last-named cables and movable transversely to points between the parallel cables, and mechanism actuating the cables whereby the burden is raised, transferred and deposited.

700,822. GAN-BOLGER. LEONARD FINE, Farmington, Cal. Filed Sept. 19, 1901. Serial No. 74,888. (No model.)

Claim.—1. The combination of a frame, a can-holder pivotally mounted in the frame, and a locking-lever fulcrumed on the frame and having a lateral arm arranged to engage the rear wall of a can in the holder.

2. The combination of a frame, a can-holder pivotally mounted at a point off its vertical center in the frame, whereby it tends to pitch in one direction, a retaining-ball 12 pivotally connected to the upper rear por-

tion of the holder, and means for normally holding the holder against pitching forwardly.

3. In a can-holder the frame 2, 3, the yoke 9 pivoted to said frame, the ball 5 pivoted to said frame and having the member 6 hinged thereto, the ball 10 attached to the ball 5, the stop 11 attached to said ball, and the retaining-ball 12, in combination, all arranged and operating substantially as shown and described and for the purposes set forth herein.

4. In a can-holder, the combination with two frames rigidly fixed to a board or platform of a can-supporting yoke 9 and ball 5 pivoted to said frame, said ball 5 having the hinged member 6, the stop 11 adjustably attached to the yoke or ball, the ball 12 pivoted to the ball 5, and the ball 13 14 15 pivoted to the post 3, all arranged and operating substantially as shown and described and for the purposes specified.

700,828. FACHS-GARRETT. WHITFIELD S. GILSON, New York, N. Y. Filed Feb. 13, 1902. Serial No. 94,732. (No model.)

Claim.—1. In a package-carrier the combination of a container; a hinged closure therefor at one end; a station-indicator carried by said closure and consisting of a plate having station characters thereon, and an aperture disk rotatably mounted on said plate; and means for locking the closure by the rotation of said disk.

2. In a package-carrier the combination of a container; a hinged closure therefor at one end; a station-indicator carried by said closure and consisting of a plate having station characters thereon, and an aperture disk rotatably mounted on said plate; means for locking the closure by the rotation of said disk; and a common handle for the closure and for the indicator.

3. In a package-carrier the combination of a cylindrical container; a circular hinged closure therefor at one end; a station-indicator carried by said closure, said indicator consisting of a series of station characters marked on said closure, and an aperture disk rotatably mounted on the closure so as to expose any given station character through its aperture, and having a notch in its periphery; an inwardly-projecting lug on the container at its closure end and designed to pass through the notch in said disk when the closure is moved into closed position and, when the said disk is thereafter rotated, to hold the closure in closed position.

4. In a package-carrier the combination of a cylindrical container; a circular hinged closure therefor at one end arranged to fit within the end of said container; a station-indicator carried by said closure, said indicator consisting of a series of station characters marked on said closure, and an aperture disk rotatably mounted on the closure so as to expose any given station character through its aperture, said disk being slightly larger in diameter than the closure, and having a notch in its periphery; an inwardly-projecting lug on the container at its closure end and designed to pass through the notch in said disk when the closure is moved into closed position and, when the said disk is thereafter rotated, to hold the closure in closed position.

5. In a package-carrier the combination of a cylindrical container; a circular hinged closure therefor at one end; a station-indicator carried by said closure, said indicator consisting of a series of station characters

marked on said closure, and an aperture disk rotatably mounted on the closure so as to expose any given station character through its aperture, and having a notch in its periphery; an inwardly-projecting lug on the container at its closure end and designed to pass through the notch in said disk when the closure is moved into closed position and, when the said disk is thereafter rotated, to hold the closure in closed position; and a common handle for the closure and for the indicator.

6. In a package-carrier the combination of the cylindrical container 1; a hinged closure-plate 4 having station characters thereon; an aperture disk 9 having a notch 11; a lug 8; a handle 6 and ball 7, substantially as set forth.

700,824. SAGE-BOLGER. EDWARD E. GRAY, Chicago, Ill. Filed May 21, 1902. Serial No. 17,302. (No model.)

Claim.—An actuating device, consisting of a rectangular plate of flexible sheet metal, having an integral tongue cut and stamped up therefrom and disposed at an angle thereto, the free end of the tongue being bent in a plane substantially at right angles to the plate, to facilitate the insertion and removal of the device between the vibrating sash and an adjacent part of a window, substantially as described.

700,825. PENDING DEVICE FOR MINERAL-WORKING MACHINERY. THOMAS S. HALL, New Haven, Conn. Filed May 14, 1902. Serial No. 62,222. (No model.)

Claim.—1. In a device of the class specified, the hopper supported at the bottom, a substantially vertical shaft forming a continuation of the hopper-mouth, a shaft journaled on the hopper, a weighted arm for causing said shaft to turn normally in one direction, means for intermittently raising said arm, and fingers secured to said shaft and adapted to normally interrupt the opening from the hopper into the chute.

2. In a device of the class specified, the combination with the hopper, a shaft journaled thereon, and fingers secured to said shaft and adapted to be brought into contact with the contents of the hopper, of means for causing said shaft to rotate comprising a weighted lever secured to said shaft and a spring connection between said lever and a superimposed intermittently-moving member.

3. In a device of the class specified, the hopper supported at the bottom and opening into a substantially vertical chute, means for periodically interrupting the opening from the hopper to the chute, a plunger adapted to move longitudinally of the chute at the bottom thereof, and a spring-actuated guard-plate normally closing the end of the chute opposite the plunger, substantially as described.

700,826. COMBINED MINERAL-PROTRACTOR, SQUARE AND PITCH-BOARD. BENJAMIN D. HARRIS, West Gardner, Mass. Filed Dec. 24, 1901. Serial No. 57,194. (No model.)

Claim.—1. In a device of the character described, the combination with the segmental part having a scale and working edges, of an index-arm having a beam pivoted at the vertex portion of said part and formed with a vane, a blade having a groove and adapted to rest in said vane, a clamping-block mounted upon the beam and having a tongue to engage said groove, means for holding the block against turning, and means for causing the block in clamping position to fix the blade to the arm, substantially as described.

2. In a device of the character described, the combination with the segmental part having a scale and working edges; of an index-arm having a beam pivoted at the vertex portion of said part and formed with a

vane, a blade having a groove and adapted to rest in said vane, a clamping-block mounted upon the beam and having a tongue to engage said groove, a screw passing downwardly through the beam and segmental part and carrying a clamping-nut, and a second screw passing upwardly through the beam and clamping-block, said screws having an interlocking engagement to prevent rotation thereof, substantially as described.

3. In a device of the character described, the combination of the segmental part provided at its vertex portion with a socket or depression and in its working edges with grooves communicating with said depression, an index-arm having a beam pivoted to turn in the socket or depression, a blade adapted to fit and slide in either of the aforesaid grooves in the working edges, and means for clamping the blade to the beam of the index-arm, substantially as set forth.

700,827. APPARATUS FOR CLEANING COFFEE-BERRIES. WILLIAM A. HARRISON, San Francisco, and HENRY J. HARRISON, Oakland, Cal., assignors to Geo. W. Corwell Company, San Francisco, Cal., a Corporation of California. Filed Jan. 14, 1901. Serial No. 68,167. (No model.)

Claim.—1. The combination with a mixing-cylinder, of a separating-cylinder, means for imparting rotation to said cylinder, a rotatable head for each cylinder capable of movement independently of the cylinder, a shaft carried by each head adapted to be adjusted therewith to discharge material from the mixing-cylinder into the separating-cylinder, and means for holding the heads against movement, substantially as described.

2. In combination substantially as described a mixing-cylinder, means for rotating the same, a separating-cylinder adjacent to the mixing-cylinder, a head formed with an internal gear-ring at one end of the separating-cylinder, gearing between said head and mixing-cylinder, the rotating means for the mixing-cylinder adapted to simultaneously rotate the separating-cylinder, and an independently-rotatable head at the free end of the separating-cylinder adapted to be adjusted to afford an inlet and an outlet for the material to be treated, substantially as described.

3. In combination substantially as described, a mixer and a separator located therebetween, independently-rotatable heads at adjacent ends of said mixer and separator arranged in substantial alignment, and means on the heads adapted to be adjusted therewith to discharge material from the mixer into the separator.

700,828. TOOL FOR OIL-WEELS OR ARTESIAN WELLS. ANDREW H. HARRINGTON, Covington, Ohio, assignor of two-thirds to W. E. Hunt and E. W. Stevenson, Marietta, Ohio. Filed Aug. 22, 1901. Serial No. 72,224. (No model.)

Claim.—1. In a device of the character described, an outer casing, an upper and a lower section comprising the inner casing, a spring encircling said lower section and secured to the upper section, a plunger-rod operating through the inner casing, and means carried by the upper section for engaging said plunger-rod, said means being operated by the outer casing for automatically releasing said plunger-rod, substantially as described.

2. In a device of the character described, an outer cylindrical casing carrying a cone-shaped portion at its upper end, an upper and a lower section comprising the inner casing mounted within the outer casing and having a coil-spring secured to each, spring-pressed jaws carried by the upper end of the inner casing, and a plunger-rod carrying a cone-shaped enlarged portion for engagement with said jaws, substantially as described.

3. In a device of the character described, the combination of an outer cylindrical casing carrying a cone-shaped portion at its upper end, an upper and a lower section comprising the inner casing, a coil-spring surrounding said lower inner casing connected at the lower portion thereof, and extending to the lower portion of the outer casing, the other end of said spring being rigidly secured to the lower portion of the upper inner casing, spring-pressed jaws secured in said upper inner casing, and a plunger-rod carrying a cone-shaped enlarged portion for engagement with said jaws, substantially as set forth.

4. In a device of the character described, an outer casing having an inner casing secured therein, the inner casing comprising two sections having a spring connected to each, a plunger-rod operating through the inner casing, spring-pressed jaws carried by one of said sections, and means carried by the plunger-rod for engagement with said jaws, said jaws being actuated by said outer casing for releasing the plunger-rod, substantially as described.

5. The combination with a plunger-rod operating through an outer casing, of an inner casing in the outer casing and through which the plunger-rod operates, the inner casing comprising two sections surrounded by a spring the ends of which are secured to said sections, means carried by one of said sections for engagement with the plunger-rod, said means being operated by the outer casing for releasing the plunger-rod, substantially as described.

6. In a device of the character described, an outer casing surrounding an inner casing, with a plunger-rod operating through both, the inner casing comprising a lower section secured to the outer casing, and an upper section movable with the plunger-rod, a spring having its ends secured to the said sections, means carried by the upper section for engagement with the plunger-rod, the said means being actuated by engagement with the outer casing, substantially as described.

700,899. FASTER FOR SATONELLA, FURMAN, JR. AND KIRK, and JAMES KIRK, Offenbach-on-the-Main, Germany, assignors to THE FIRM OF R. F. HUBEL, Offenbach-on-the-Main, Germany. Filed Feb. 25, 1900. Serial No. 93,993. (No model.)

Claim.—1. In a fastener for catches, pins and the like, the combination with a frame consisting of two halves, of two plates or wings, one of which is secured to one half of the frame, a hinge between said plates to which is secured to one half of the frame, a hinge between said plates to which the other plate is secured, said latter plate having an aperture adapted to be engaged by a catch or pin on the second half of the frame, substantially as described.

2. In a fastener for catches, pins and the like, the combination with a frame consisting of two halves, of two plates or wings, one of which is secured to one half of the frame, a hinge between said plates to which is secured to one half of the frame, a hinge between said plates to which the other plate is secured, said latter plate having an aperture adapted to be engaged by a catch or pin on the second half of the frame, substantially as described.

3. In a fastener for catches, pins and the like, the combination with a frame consisting of two halves, of two plates or wings, one of which is secured to one half of the frame, a hinge between said plates to which is secured to one half of the frame, a hinge between said plates to which the other plate is secured, said latter plate having an aperture adapted to be engaged by a catch or pin on the second half of the frame, substantially as described.

4. In a fastener for catches, pins and the like, the combination with a frame consisting of two halves, of two plates or wings, one of which is secured to one half of the frame, a hinge between said plates to which is secured to one half of the frame, a hinge between said plates to which the other plate is secured, said latter plate having an aperture adapted to be engaged by a catch or pin on the second half of the frame, substantially as described.

5. In a fastener for catches, pins and the like, the combination with a frame consisting of two halves, of two plates or wings, one of which is secured to one half of the frame, a hinge between said plates to which is secured to one half of the frame, a hinge between said plates to which the other plate is secured, said latter plate having an aperture adapted to be engaged by a catch or pin on the second half of the frame, substantially as described.

700,880. MACHINE FOR COMPOSING TABULAR MATTER. HARVEY C. INGRAM, Philadelphia, Pa., assignor, by mesne assignments, to Lanston Monotype Machine Company, Washington, D. C., a Corporation of Virginia. Filed Oct. 24, 1901. Serial No. 78,968. (No model.)

Claim.—1. A mechanically-justified record strip or controller for automatic type-composing machines formed or provided with a plurality of type-designating signals or perforations arranged in series, each of the latter representing a line of composition divided into sections of predetermined lengths and preceded by its appropriate justification signal or perforation, and a special line-signal intermediate adjacent series of type-designating signals or perforations, substantially as described.

2. A record strip or controller for setting up mechanically-justified lines in an automatic type-composing machine in which the type-designating signals or perforations representing a line are separated by justification-designating signals or perforations and the lines are operated by justification-designating signals or perforations and a galley-signal; substantially as described.

3. In an automatic type-composing machine governed by a record strip or controller containing justification and type designating signals or perforations serially arranged to produce mechanically-justified lines of com-

position, and a special line-signal intermediate adjacent lines, the combination with said record strip or controller of a galley-trip mechanism actuated by the justification signal and responsive to the special line-signal, whereby each line as composed may be divided into separately-justified sections and the latter assembled into a line prior to its transfer to the galley; substantially as described.

4. In a machine of the character described for producing mechanically-justified lines of type and assembling said lines in columns, the combination with the justification-designating device and a galley-starting mechanism responsive to the combined action of said designating device but to neither one alone, of a record strip or controller provided with means for simultaneously actuating said designating device to start the galley mechanism at the end of a line and transfer the latter to the galley, substantially as and for the purpose specified.

5. In a machine such as described, the combination with a plurality of justification-designating levers and a galley-starting lever, of intermediate transmitting devices central to the movements of either designating-lever alone or as far as the starting of the galley mechanism is concerned, but responsive to the joint action of said designating-levers.

6. In an automatic type-composing machine wherein the selection of type and composition and justification of the lines is governed by a record strip or controller containing designating signals or perforations, the combination therewith of a record strip or controller wherein type-designating signals or perforations are serially arranged in the order of composition, and separated into series representing consecutive sections and complete lines, the lines by character justification-designating signals and the sections by normal justifying-designating signals, and a galley-controlling mechanism central to the normal justification-signals but responsive to the character justification-designating signals, substantially as and for the purpose specified.

700,881. GRAB-CLIPPER AND MATCH-LIGHTER. BENNETT R. JACK, Chicago, Wis., assignor of one-half to Herman Mueller, Horton, Wis. Filed Aug. 21, 1901. Serial No. 74,988. (No model.)

Claim.—1. In combination a hopper to contain matches, a grooved roller to receive matches from the hopper and deliver the same, a rough plate in the path of movement of the heads of the matches being delivered, and a delivery-champ in the path of movement of the roller to receive the matches therefrom, substantially as described.

2. In a mechanism of the class described, the combination with a suitable support, of a roller mounted therein, means for supplying articles thereto, means on said roller for carrying a single article, means for rotating said roller for delivering the article carried thereby, and automatic means for oscillating said roller after each delivery, substantially as described.

3. In a mechanism of the class described, the combination with a suitable support, of a roller mounted therein, means on said roller for carrying an article, means for supplying articles to said roller, means for rotating said roller for delivering the article carried thereby, and means for receiving the article to be delivered and removing the same from said roller and carrying the same to the point of delivery, substantially as described.

4. In a mechanism of the class described, the combination with a suitable framework, of a roller mounted therein, an article-containing hopper arranged above said roller, means on said roller for receiving a single article from said hopper, means for rotating said roller, a delivering-arm pivotedly mounted in said framework, and means for swinging said arm into the path of movement of said article for receiving and carrying the same to the point of delivery, substantially as described.

5. In a mechanism of the class described, the combination with a suitable framework, provided with a supply-receptacle, of a roller mounted in said framework and communicating with said receptacle, means on said roller for receiving an article from said receptacle, means for rotat-

ing said roller for removing the article from said receptacle, and auxiliary means for removing said article from said roller and carrying the same to the point of delivery, substantially as described.

6. In combination a hopper for containing matches, a grooved roller for receiving them therefrom, a shaft carrying the roller, a disk on the shaft, lateral legs on the disk, means for rotating the shaft, a clamp to receive the matches carried by the roller, and means operated by the lateral legs for bringing the clamp into operative receiving position, substantially as described.

7. In combination, a hopper for containing matches, a shaft, a grooved roller carried thereby to receive matches from the hopper, a disk on the shaft, radial arms on the shaft, a vertical plunger, a leg thereon to engage the arms, a clamp to receive the matches from the roller, and means for moving the clamp into receiving position and returning it to delivery position, substantially as described.

8. In combination, a hopper for containing matches, having an open bottom, a grooved roller mounted under the hopper, means for rotating the roller forward to deliver a match, and spring-controlled means for automatically oscillating the roller after each delivery for returning the matches in the hopper, substantially as described.

9. In combination, a hopper for containing matches, having an open bottom, a shaft, a grooved roller thereon under the hopper, a plunger, connections between the roller and plunger for rotating the roller forward by the depression of the plunger, and means for imparting several backward-and-forward partial rotations to said roller during the upward movement of the plunger, substantially as described.

10. In combination, a hopper for containing matches, having an open bottom, a shaft, a grooved roller upon the shaft under the hopper, a plate on the shaft, radial arms on said plate, a plunger, a lateral projection or leg thereon, a vertically-slidable rod having its upper end bent into the path of movement of the lateral leg and its lower end bent into the path of movement of the radial arm, the contact of the lateral leg during its downward movement with the arm of the plate serving to rotate the shaft and roller forward to deliver a match, and its contact with an arm and the upper end of the vertical rod serving to reciprocally rotate the roller during the upward movement of the plunger and leg, substantially as described.

11. In a mechanism of the class described, the combination with a suitable framework, of a shaft mounted therein, a roller fixed to said shaft, radial arms carried by said shaft, means for engaging one of said arms for swinging the same and the shaft for a portion of a rotation, means for engaging another of said arms for swinging the same and said shaft in an opposite direction for returning the roller to the initial position after the first operation, and means for delivering a single article at each initial operation of the roller, substantially as described.

12. In a mechanism of the class described, the combination with a suitable framework, of a shaft mounted therein, a delivery-roller arranged on said shaft, radial arms extending from said shaft and secured thereby, a vertically-movable rod mounted in said framework, means carried thereby for engaging one of said radial arms of said shaft, and auxiliary means for imparting a return rotation to said shaft after the operation of said vertical rod whereby the said roller will be oscillated, substantially as described.

13. In a mechanism of the class described, the combination with a suitable framework, of a shaft mounted therein, a delivery-roller carried thereby, radial arms secured to said shaft, means for engaging said arms for swinging the same in one direction, means for swinging the same in another direction whereby the delivery-roller will be oscillated, a delivering-arm pivotedly supported in said framework, and means for swinging said arm in position to receive an article from the said roller, substantially as described.

14. In a mechanism of the class described, the combination with a suitable framework, of a shaft mounted therein, a delivery-roller carried by said shaft, a disk also carried by the shaft provided with laterally-projecting legs, a delivering-arm pivotedly supported in said framework and having one end thereof extending into the path of movement of said legs, and means for rotating said shaft for delivering an article to said delivering-arm, substantially as described.

15. In a mechanism of the class described, the combination with a suitable framework, of a shaft supported therein, means carried by said shaft for operating an article from a series of similar articles, a delivering-arm pivotedly mounted in said framework, and means carried by said shaft for swinging said delivering-arm into position for receiving the article separated, substantially as described.

16. In a mechanism of the class described, the combination with a suitable framework, of a shaft supported therein, article-delivering means carried by said shaft and designed to be operated by the rotation thereof, radial arms extending from said shaft, a vertically-movable rod mounted in said framework and provided with means designed to engage one of said arms at each downward movement of said rod, whereby said shaft

is designed to be forwardly rotated, the construction being such that downward movement of said rod will move the next succeeding radial arm into the path of the movement of said engaging means, whereby the said next succeeding arm is designed to be engaged and swung in an opposite direction with the upward movement of said rod to that of its former movement with the downward movement of said rod, and auxiliary means for engaging another of said radial arms for swinging the same in the direction of its initial movement after the second movement thereof, substantially as described.

17. In a mechanism of the class described, the combination with a suitable framework, of a shaft mounted therein and carrying article-delivering means, radial arms secured to said shaft, a vertically-movable rod arranged in said framework, a lag projecting laterally from said rod adapted to contact with one of said radial arms with the downward movement of said rod for swinging said arm forwardly and bringing the next succeeding radial arm into the vertical plane of said rod whereby a return movement of the lag is designed to strike the next succeeding arm and swing the same in an opposite direction to the forward movement, and auxiliary means for again swinging the shaft in the direction of its forward movement during the return of said vertical rod to its normal position, substantially as described.

18. In a mechanism of the class described, the combination with a suitable framework, of a shaft mounted therein, radial arms fixed to said shaft, a vertically-movable rod arranged in said framework, a lag extending laterally from said rod, adapted to contact with one of said radial arms, a bent rod slightly supported in said framework and having one end extending in the vertical plane of and above said lag, and the other end normally extending into the path of movement of said radial arms, said bent rod being free to move downwardly by its own weight with the downward movement of the lag, and means limiting the movement of said bent rod, substantially as described.

700,882. PULLING-OVER MACHINE. JAMES E. JAMISON, Lynn, Mass., assignor, by mesne assignments, to United Shoe Machinery Company, Paterson, N. J., and Boston, Mass., a Corporation of New Jersey. Filed Jan. 20, 1904. Serial No. 64,572. (No model.)

Claim.—1. A pulling-over machine having a gripper one jaw of which is fixed, and an automatically-operated member for forcing the last away from the gripper to stretch the upper, said automatically-operated member being located at a distance from the gripper to permit the last to be reeled on said member by the operator to manually control the amount of stretch.

2. A pulling-over machine having a gripper one jaw of which is fixed, an automatically-operated member for forcing the last away from the gripper to stretch the upper, and means for automatically operating the movable jaw of the gripper, the said automatically-operated member being located at a distance from the gripper to permit the last to be reeled on said member by the operator to manually control the amount of stretch.

3. A pulling-over machine having a gripper for the edge of the upper, one jaw of the gripper being fixed, an abutment against which the bottom of the last is held by the operator, and means for supporting the abutment, the said abutment being located at a distance from the gripper to permit the last to be reeled thereon by the operator to manually control the amount of stretch.

4. A pulling-over machine having a gripper for the edge of the upper, an abutment against which the bottom of the last is held by the operator, and relatively to which the last may be moved to lay the edge of the upper over the last, and means for moving the abutment to free the last away from the gripper, the said abutment being located at a distance from the gripper to permit the last to be reeled by the operator to manually control the amount of stretch.

5. A pulling-over machine comprising an automatic gripper one jaw of which is fixed, automatic means cooperating with said gripper to stretch the upper, relatively to which means the last is movable in a direction lateral to the direction of pull, and automatic mechanism for forcing the upper to the last.

6. A pulling-over machine comprising a stationary wiper, a gripper, a device cooperating with the gripper to stretch the upper and movable in a direction to stretch said upper while held by the gripper, and means for automatically operating said gripper and said stretching device.

7. A pulling-over machine comprising upper-stretching mechanism and a stationary wiper, mechanism for forcing the upper to the last, and a gage pivoted to said wiper and bodily movable into inoperative position above the plane of said wiper to permit the stretching mechanism to operate on the shaft of the partially-formed shoe.

700,883. TREAD FOR WHEELS. WILLIAM L. JONES, Chicago, Ill. Filed Sept. 21, 1904. Serial No. 78,014. (No model.)

Claim.—1. The combination with a wheel, of a tread therefor comprising a series of shoes mounted for rolling engagement with the periphery of said wheel, and reversely-extending pairs of flexible connections attached at their inner ends to the said wheel, following the periphery thereof at their intermediate portions and attached at their outer ends to the opposite free ends of said shoes, substantially as described.

2. The combination with a wheel having a peripheral shoe-guiding flange, of a series of shoes mounted for rolling engagement with the periphery of said wheel and guided by said flange, and reversely-extending pairs of flexible connections attached at their inner ends to said wheel, following the periphery thereof at their intermediate portions and attached at their outer ends to the opposite free ends of said shoes, substantially as described.

3. The combination with a wheel, of a series of shoes having rolling engagement with the periphery of said wheel, loosely-pivoted retaining-balls connecting the central portions of said shoes to the periphery of said wheel with freedom for rocking movements, and reversely-extending pairs of flexible connections attached at their inner ends to said wheel, following the periphery thereof at their intermediate portions and attached at their outer ends to the opposite free ends of said shoes, substantially as described.

4. The combination with a wheel having a peripheral shoe-guiding flange, of a series of shoes having rolling engagement with the periphery of said wheel and guided by said flange, and reversely-extending pairs of flexible connections attached at their inner ends to the periphery of said wheel with freedom for rocking movements, and reversely-extending pairs of flexible connections attached at their inner ends to said wheel, following the periphery thereof at their intermediate portions and attached at their outer ends to the opposite free ends of said shoes, substantially as described.

5. The combination with a wheel having peripheral shoe-guiding flange, of shoes in staggered arrangement guided by said flange, and retaining-balls loosely pivoted to the central portions of said shoes and passed through the periphery of said wheel, substantially as described.

6. The combination with a wheel, of a series of shoes having rolling engagement with the periphery of said wheel, reversely-extending pairs of flexible connections attached at their inner ends to said wheel, following the periphery thereof at their intermediate portions and attached at their outer ends to the opposite free ends of said shoes, and means for adjusting said flexible connections to take up slack, substantially as described.

7. The combination with a wheel having a peripheral shoe-guiding flange, of a series of shoes mounted for rolling engagement with the periphery of said wheel and guided by said flange, and reversely-extending pairs of flexible connections attached at their inner ends to said wheel at their inner ends, following the periphery thereof at their intermediate portions and attached at their outer ends to the opposite free ends of said shoes, substantially as described.

700,884. COMBINED FASTENER AND COVER-CLAY FOR BOXES. JOHN C. GARDNER, Albany, Kansas, Kansas City, Mo. Filed Sept. 2, 1904. Serial No. 74,809. (No model.)

Claim.—A combined spring-fastener and cover-clay for boxes, comprising a casing having three plates arranged in three planes and secured to a corner of the box, a stretched upwardly-extending elastic integral with said casing, an opening in the lid of the box to receive said elastic when the lid is closed, a housing secured to the lid over said opening, and a spring-bolt in said housing, said bolt having a slot therein to receive said elastic, substantially as described.

700,885. MEANS FOR VENTILATING CORES FOR ELECTRICAL APPARATUS. JOHN B. KIMBLE, New York, N. Y. Filed May 21, 1904. Serial No. 61,509. (No model.)

Claim.—1. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a dust which extends therethrough, said dust extending in the general direction of and being so positioned with respect to the axis of rotation of the core that a current of air is caused to flow through it when the core is rotated, the mouth of the dust being so shaped as to cause air to flow therethrough, substantially as described.

2. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a plurality of dusts which extend in the general direction of and are so positioned with respect to the axis of rotation of the core that currents of air are caused to flow through them when the core is rotated, the mouths of the dusts being so shaped as to cause air to flow into the dusts, substantially as described.

3. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a dust which extends therethrough, the axis of said dust extending in the general direction of but not being parallel with the axis of rotation of the core, and said dust having a mouth so shaped as to cause air to flow into it, substantially as described.

4. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a plurality of dusts which extend therethrough, the axes of said dusts extending in the general direction of but not being parallel with the axis of rotation of the core, substantially as described.

5. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a dust the axis of which extends in the general direction of but is not parallel with the axis of rotation of the core, and said dust having a mouth so shaped as to cause air to flow into it, substantially as described.

6. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a plurality of dusts, the axes of which extend in the general direction of but are not

parallel with the axis of rotation of the core, and said dusts having mouths so shaped as to cause air to flow into them, substantially as described.

7. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a dust extending therethrough, the axis of said dust extending in the general direction of but not being parallel with the axis of rotation of the core, and said dust having a mouth so shaped as to cause air to flow into it, substantially as described.

8. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a plurality of dusts extending therethrough, the axes of which extend in the general direction of but are not parallel with the axis of rotation of the core, and said dusts having mouths so shaped as to cause air to flow into them, substantially as described.

9. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a dust which extends in the general direction of and is so positioned with respect to the axis of rotation of the core that a current of air is caused to flow through it when the core is rotated, substantially as described.

10. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a dust which extends therethrough, said dust extending in the general direction of and being so positioned with respect to the axis of rotation of the core that a current of air is caused to flow through it when the core is rotated, substantially as described.

11. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a plurality of dusts which extend in the general direction of and are so positioned with respect to the axis of rotation of the core that currents of air are caused to flow through them when the core is rotated, substantially as described.

12. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a plurality of dusts extending therethrough, said dusts extending in the general direction of and being so positioned with respect to the axis of rotation of the core that currents of air are caused to flow through them when the core is rotated, substantially as described.

13. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a dust which extends in the general direction of and is so positioned with respect to the axis of rotation of the core that a current of air is caused to flow through it when the core is rotated, the mouth of the dust being so shaped as to cause air to flow therethrough, substantially as described.

14. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a dust which extends therethrough, said dust extending in the general direction of and being so positioned with respect to the axis of rotation of the core that a current of air is caused to flow through it when the core is rotated, the mouth of the dust being so shaped as to cause air to flow therethrough, substantially as described.

15. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a plurality of dusts which extend in the general direction of and are so positioned with respect to the axis of rotation of the core that currents of air are caused to flow through them when the core is rotated, the mouths of the dusts being so shaped as to cause air to flow into the dusts, substantially as described.

16. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated to form a plurality of dusts extending therethrough which extend in the general direction of and are so positioned with respect to the axis of rotation of the core that currents of air are caused to flow through them when the core is rotated, the mouths of the dusts being so shaped as to cause air to flow into the dusts, substantially as described.

17. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated in a helical direction, whereby as the core rotates a current of air is caused to flow through the dust thus formed, substantially as described.

18. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated in a helical direction, whereby as the core rotates currents of air are caused to flow through the dusts thus formed, substantially as described.

19. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated in a helical direction so as to form a dust extending therethrough, whereby as the core rotates a current of air is caused to flow through the dust thus formed, substantially as described.

20. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated in helical directions so as to form a plurality of dusts extending therethrough, whereby as the

core rotates currents of air are caused to flow through the ducts thus formed, substantially as described.

21. A rotating core or similar rotating part for use with electrical apparatus the material of said core being perforated in a helical direction, whereby as the core rotates a current of air is caused to flow through the duct thus formed, and the mouth of the duct being so shaped as to cause air to flow into the duct, substantially as described.

22. A rotating core or similar rotating part for use with electrical apparatus the material of said core being perforated in helical directions, whereby as the core rotates currents of air are caused to flow through the ducts thus formed, and the mouths of the ducts being so shaped as to cause air to flow into the ducts, substantially as described.

23. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated in a helical direction so as to form a duct extending therethrough, whereby as the core rotates a current of air is caused to flow through the duct thus formed, and the mouth of the duct being so shaped as to cause air to flow into the duct, substantially as described.

24. A rotating core or similar rotating part for use with electrical apparatus, the material of said core being perforated in helical directions so as to form ducts extending therethrough, whereby as the core rotates currents of air are caused to flow through the ducts thus formed, and the mouths of the ducts being so shaped as to cause air to flow into the ducts, substantially as described.

25. A rotating core or similar rotating part for use with electrical apparatus having a helical duct located therein, the axis of the helix formed by the duct being coincident with the axis of rotation of the core, substantially as described.

26. A rotating core or other similar rotating part for use in electrical apparatus having a plurality of helical ducts located therein, the axis of the helices formed by said ducts being coincident with the axis of rotation of the core, substantially as described.

27. A rotating core or other similar rotating part for use in electrical apparatus having a plurality of helical ducts extending therethrough, the axis of the helices formed by said ducts being coincident with the axis of rotation of the core, substantially as described.

28. A rotating core or similar rotating part for use with electrical apparatus having a helical duct located therein, the axis of the helix formed by said duct being coincident with the axis of rotation of the core, and the mouth of said duct being so shaped as to cause air to flow into the duct, substantially as described.

29. A rotating core or other similar rotating part for use in electrical apparatus having a plurality of helical ducts located therein, the axis of the helices formed by said ducts being coincident with the axis of rotation of the core, and the mouths of said ducts being so shaped as to cause air to flow into the ducts, substantially as described.

30. A rotating core or other similar rotating part for use in electrical apparatus having a plurality of helical ducts extending therethrough, the axis of the helices formed by said ducts being coincident with the axis of rotation of the core, and the mouths of said ducts being so shaped as to cause air to flow into the ducts, substantially as described.

31. A rotating core or other similar rotating part for use in electrical apparatus comprising a plurality of perforated disks mounted on a shaft, said disks being so arranged that the perforations form a helical duct or ducts, substantially as described.

32. A rotating core or similar rotating part for use in electrical apparatus comprising a plurality of perforated disks mounted on a shaft, said disks being so arranged that the perforations form a helical duct or ducts extending through the core, substantially as described.

33. The combination with the casing of an electrical apparatus, such as a motor, generator or rotary transformer, of a rotating core mounted therein, the material of said core being perforated to form a helical duct or a plurality of such ducts, and means for admitting air to and permitting it to escape from the casing, substantially as described.

34. The combination with the casing of an electrical apparatus, such as a motor, generator or rotary transformer, of a rotating core mounted therein, the material of said core being perforated to form a helical duct or a plurality of helical ducts extending therethrough, and means for admitting air to and permitting it to escape from the casing, substantially as described.

35. The combination with the casing of an electrical apparatus, such as a motor, generator or rotary transformer, of a rotating core mounted therein, the material of said core being perforated to form a helical duct or a plurality of such ducts, the mouths of the ducts being so shaped as to cause air to flow into the ducts, and means for admitting air to and permitting it to escape from the casing, substantially as described.

36. The combination with the casing of an electrical apparatus, such as a motor, generator or rotary transformer, of a rotating core mounted therein, the material of said core being perforated to form a helical duct or a plurality of helical ducts extending therethrough, the mouths of the ducts being so shaped as to cause air to flow into the ducts, and means

for admitting air to and permitting it to escape from the casing, substantially as described.

37. The combination with the casing of an electrical apparatus, such as a motor, generator or rotary transformer, of a rotating core mounted therein, the material of said core being perforated to form a helical duct or a plurality of helical ducts extending therethrough, the axis of the helices formed by the ducts being coincident with the axis of rotation of the core, and the mouths of said ducts being so shaped as to cause air to flow into the ducts, and means for admitting air to and permitting it to escape from the casing, substantially as described.

38. A disk for use with a rotating core or similar rotating part of electrical apparatus, said disk being perforated and the material of said disk adjacent to the perforation being forced outward to form a vane to direct air into the perforation, substantially as described.

39. A rotating core or other similar rotating part for use in electrical apparatus comprising a plurality of perforated disks, the perforations of which are arranged to form a helical duct or ducts, the material of the said disks adjacent the perforations being forced outward to form vanes to direct air into the perforations, substantially as described.

700,886. TYPE-COMPOSING MACHINES FOR TABULAR MATTER. WILLIAM KEMP, JR., New York, N. Y., assignor to Lanston Monotype Machine Company, New York, N. Y., a Corporation of Virginia. Filed Jan. 28, 1902. Serial No. 90,902. (No model.)

Claim.—1. In an automatic type-composing machine the combination with means for forming a line of type in successive justified sections and a galley in which successive sectionally-justified lines are assembled in column, of means for automatically transferring each complete sectionally-justified line to said galley; substantially as described.

2. In a type-composing machine provided with mechanism for automatically composing and justifying successive sections of type and assembling said sections as a complete line, and in combination therewith a line-transfer provided with means for automatically actuating the same upon the completion of each line, whereby successive sectionally-justified lines are assembled in column form, as and for the purpose specified.

3. In a type-forming machine provided with means for automatically forming successive type in the order of composition and assembling them in sectionally-justified lines and in combination therewith a column holder or galley and a line-transfer provided with means for automatically delaying its action until the plurality of sections composing each line have been separately formed, justified and assembled in line; substantially as described.

4. In a type-composing machine such as described the combination with the type-composing line-section justifying and line-assembling mechanism and a column-forming galley, of a line-transfer provided with a timing mechanism for defining the periods of line-transfer.

5. The combination with a type-composing machine provided with type-assembling and line-section justifying means, and a galley mechanism including a line-transfer and a trip or starting device thereof, of an adjustable or variable automatic timing mechanism for actuating the trip or inaugurating the movement of the starting device; substantially as described.

6. In a type-composing machine such as described, the combination with the justifying device and the galley-trip controlling the line-transfer, of an automatic timing mechanism intermediate the justifying device and the galley-trip for controlling the periods of line-transfer; substantially as described.

7. In a type-composing machine such as described, wherein the line-assembling and section-line justification are automatically governed by a controller and in combination therewith, a galley mechanism provided with a line-transfer, a starting device controlling the action of said line-transfer and a timing mechanism for said starting device governed by said controller; substantially as described.

8. In a type-composing machine such as described provided with a controller, type-ascending and line-justifying mechanism, a galley mechanism including a line-transfer and a trip thereof, and in combination therewith an automatic timing mechanism modifiedly acted upon by the controller to actuate said trip; substantially as described.

9. In a type-composing machine such as described, the combination with a galley trip-lever, of a ratchet-wheel mounted on said lever and provided with a shoulder for engagement therewith, a retracting-spring and stop for said ratchet-wheel, and a reciprocating pawl engaging said ratchet-wheel; substantially as described.

10. In a type-composing machine such as described provided with a controller, a justifying mechanism and a galley mechanism furnished with a trip-lever and in combination therewith a ratchet-wheel mounted on said trip-lever and provided with a shoulder for engagement therewith, and an actuating-pawl controlling the advance movements of said ratchet-wheel, said pawl reciprocating in unison with a portion of the justifying mechanism to effect an advance of the ratchet-wheel each time the justifying device are set for a new column; substantially as described.

11. In a type-composing machine such as described, and in combination with the galley trip-lever thereof, a ratchet-wheel carried by said lever and provided with a shoulder for engaging the same, a retracting-spring, back-stop and holding-pawl for said ratchet-wheel, and a reciprocating pawl engaging said ratchet-wheel; substantially as described.

12. In a type-composing machine such as described, and in combination with the trip-lever for cutting in action the line-transfer, a ratchet-wheel mounted on said lever and provided with a shoulder for engaging the same, a retracting-spring back-stop and holding-pawl for said ratchet-wheel, an actuating-pawl and a trip connected to the line-transfer and engaging the holding-pawl to withdraw the latter; substantially as described.

13. In a type-composing machine such as described and in combination with its justification-wedge-shifting lever and the trip-lever controlling the line-transfer, of a timing mechanism for said line-transfer the same including a pawl receiving motion from the justification-wedge lever, a ratchet-wheel mounted on the said trip-lever and adapted to engage the latter and move it after a predetermined number of reciprocations of the pawl have taken place; substantially as described.

14. In a type-composing machine such as described, and in combination with the justifying mechanism and line-transfer trip-lever, a timing mechanism for said line-transfer, the same comprising an intermittingly-acting driving member deriving motion from the justifying mechanism, and a driven member engaging the trip-lever, to actuate the latter, after a predetermined number of advance movements; substantially as described.

700,887. TWO-BOW CULTIVATOR. LUDWIG KILMER, Kansas City, Mo. Filed Feb. 22, 1898. Serial No. 99,416. (No model.)

Claim.—1. In a cultivator comprising two bows secured together by a cross-plank, shafts journaled at the rear ends of the bows and pro-

vided with shovel-beams, loop-bars secured to the adjacent ends of the bows, through which the cross-plank operates, levers pivotedly secured to the upper portions of the loop-bars, means for retaining the levers in any desired position, crank-arms secured to the adjacent ends of the shafts, and connecting-bars pivotedly secured at their opposite terminals to the levers and the crank-arms, substantially as described.

2. In a cultivator of the class described, loop-bars secured to the adjacent ends of the bows, beams secured to the rear ends thereof, shafts journaled therein carrying disks, cranks secured to the adjacent ends of said shafts, levers fulcrumed to the upper portions of the loop-bars, and connecting-bars pivotedly secured at their opposite ends to the cranks and the levers, substantially as described.

3. In a cultivator of the class described, loop-bars secured to the adjacent ends of the bows, journaled shafts mounted on the bows carrying suitable cultivating appliances, cranks secured to the adjacent ends of said shafts, levers fulcrumed to the loop-bars, and connecting-bars pivotedly secured at their opposite ends to the cranks and the levers, substantially as described.

4. In a cultivator, a cross-plank, gangs adjustably pivoted to the same, standards extending downwardly from the gang-frames, runners bent upwardly at their opposite ends and secured to the lower terminals of the standards, carrying-wheels mounted upon stub-shafts projecting from the rear standards just in the rear of the center of gravity of the machine, and means for adjusting the cross-plank so that all or any portion of the weight of the machine may be balanced on said wheels, substantially as described.

700,888. CALENDER-ROLLER. JOHANNES KLEINOWITZ, Germany, assignor to FIRM of Joh. Kleinowitsch & Co., G.m.b.H., Rheinh. Frank, Germany. Filed Feb. 12, 1899. Serial No. 47,945. (No model.)

Claim.—1. Calender-roller for smoothing purposes and for producing impressions, in which the covering forming the operative surface of the roller is composed of layers of different kinds of fibrous material.

2. A calender-roller comprising a mandrel, a covering forming the operative surface of the roller composed of several layers of different material alternating with each other, and means for holding said layers on the mandrel, substantially as described.

700,889. ROASTING-FURNACE. FRANK KLEINOWITZ and WILLIAM J. EVANS, Greentide, Mont. Filed Aug. 2, 1899. Serial No. 29,357. (No model.)

Claim.—1. In a furnace of the class described, a hearth, a roof therefor, a hopper thereabove having a constricted opening, means for rotating the material to be treated in the opening of said hopper consisting of rotary stirrer-arms projected from the upper outer edge of said hopper to the discharge-opening thereof, and separate means for feeding the material from said hopper to said hearth, substantially as set forth.

2. A roasting-furnace having a hearth and roof, a central vertical stirring-shaft therein, a stirring-arm arranged on said shaft beneath and near said roof and extending over the hearth, and an upward projection on said arm in position to remove accretions from the roof, substantially as set forth.

3. In a furnace having a plurality of hearths, a rotatable hollow shaft passing through the hearths, a series of hollow arms radiating from said shaft and extending into the several hearths, an inner water-feed pipe located within and rotatable with the shaft, a series of branches or distributing-pipes leading from said feed-pipe and communicating with the interior of the hollow arms for returning the water of circulation through the hollow shaft to a point adjacent to the feed end of the feed-pipe, substantially as set forth.

4. In a furnace having a plurality of hearths, a rotatable hollow shaft passing through the hearths, a series of hollow arms radiating from said shaft and extending into the several hearths, an inner water-feed pipe closed at the bottom, located within the shaft and rotatable therewith, a series of branches or distributing-pipes leading from said feed-pipe and communicating at their outer ends with the interior of the hollow arms, for returning the water of circulation through the hollow shaft to a point adjacent to the feed end of the feed-pipe, substantially as set forth.

5. In a roasting-furnace, a rotatable shaft, one or more arms carried thereby, flanges formed on either side of said shaft and a series of rotatable stirring-teeth embracing said flanges, substantially as set forth.

6. In a roasting-furnace, a rotatable shaft, one or more hollow arms carried thereby, said arms having a substantially plane bottom and fur-

ing peripheral walls, an inner water-feed pipe within the shaft, a series of branches or distributing-pipes leading from said feed-pipe and communicating with the interior of the hollow arms for returning the water of circulation through the arms and through the shaft to a point adjacent to the feed end of the feed-pipe, and causing the ascending currents of the water to follow the flaring walls of said hollow arms, substantially as set forth.

7. In a roasting-furnace, a rotatable shaft, one or more arms carried thereby, said arms having a flat bottom and peripheral upwardly-flaring walls, lateral flanges forming extensions of said bottom, and a series of stirring-teeth extending said flanges, substantially as set forth.

8. In a roasting-furnace having a plurality of hearths, a rotatable shaft passing through the hearths, arms radiating from said shaft, a series of stirring-teeth carried by said arms, a feed-bopper for the upper hearth, and a plurality of discharge flaps or passages leading from said upper hearth whereby uniform drying results are insured, substantially as set forth.

700,840. ELECTRICAL OUTLET-BOX. HENRY KRAMER, Brooklyn, N. Y. Filed Mar. 24, 1902. Serial No. 100,100. (No model.)

Claim.—1. An electrical outlet-box, having a split connecting-neck, one part of the neck being formed integral with the body of the box, and the other separate, and means for clamping them together, the side wall of the box at the outlet-opening being cut away, as and for the purpose described.

2. An electrical outlet-box having a split connecting-neck, one part of the neck being formed integral with the body of the box, and the other separate, and means for clamping them together, the side wall of the box at the outlet-opening being cut away, and a filling-piece being provided for said cut-away portion, substantially as described.

3. An electrical outlet-box having its side wall cut away at the outlet-opening, with a split connecting-neck, one part integral with the box, and the other a separate part which carries a filling-piece for the cut-away portion of the side wall, all substantially as described.

700,841. TYPE-COMPOSING MACHINE. TOLBERT LANGRISH, Washington, D. C., assignor to Linotype Monotype Machine Company, Washington, D. C., a Corporation of Virginia. Original application filed Mar. 6, 1901, Serial No. 60,170. Divided and this application filed Feb. 2, 1902. Serial No. 90,000. (No model.)

Claim.—1. In a machine such as described, the combination with a controller-composing mechanism and a type-composing mechanism, of a speed-controller acted upon by the controller or record-strip and acting upon the type-composing mechanism; substantially as described.

2. In a composing-machine comprising a controller, a controller-composing mechanism, and a type-composing mechanism the latter governed by the signals of the controller and in combination therewith a speed-controller for the type-composing mechanism and actuating device therefor engaged by the controller for varying the speed of the type-composing mechanism, substantially as described.

3. In a composing-machine such as described, the combination of the following elements, to wit: a manually-operated controller-composing mechanism; a power-driven automatic type-composing mechanism; a controller connecting the said composing mechanisms; and means operated upon by the controller for varying the speed of the type-composing mechanism; substantially as described.

4. In a composing mechanism such as described, the combination of the following elements, to wit: an automatic type-composing mechanism; a controller governing said type-composing mechanism; a controller-composing mechanism arranged to deliver the controller directly to said type-composing mechanism; a speed-controller for the type-composing mechanism; and a governing member for said speed-controller engaged by the controller at a point intermediate said controller-composing and type-composing mechanism; substantially as described.

5. In a composing-machine such as described, the combination of the following elements, to wit: type-composing mechanism; an electric motor therefor; controller-composing mechanism; a speed-controller, such as a rheostat, connected to said motor; and a control system or mechanism for said speed-controller in position to be acted upon by the controller or record-strip; substantially as described.

6. In a composing-machine such as described, the combination with a type-composing mechanism governed by a controller and provided with feed devices for the latter located in proximity to the galley, of a controller-composing mechanism delivering the controller directly to the feed devices of the type-composing mechanism and located in front of the latter so that the operator at the controller-composing mechanism may supervise and superintend the running of the type-composing mechanism.

700,842. CHAIN CONVEYER. GREGORY W. LEVALL, New York, N. Y. Original application filed Nov. 12, 1900, Serial No. 60,000. Divided and this application filed Sept. 27, 1902. Serial No. 91,000. (No model.)

Claim.—1. In a conveyer, the combination with a chain formed of articulating links having side bars, of anti-friction-wheels attached to the side bars of the chain intermediate of the joints or articulating parts thereof, substantially as set forth.

2. In a conveyer, the combination with a chain formed of articulating links having side bars, the side bars of certain of the links being provided, between their ends, with supporting-wings, of anti-friction-wheels, and

wheel-carriers therefor supported by the said wings of the chain-links, substantially as set forth.

3. In a conveyor, the combination with a chain formed of articulated links, of antifriction supporting-wheels for the chain connected directly with the links thereof and arranged laterally outside of or beyond the sides of the chain, substantially as set forth.

4. In a conveyor, the combination with a chain composed of articulated links having side bars, of antifriction-wheels adapted to support the chain, the said wheels being attached to the side bars intermediate of the articulating parts of the chain and being arranged outside of or beyond the side edges of the chain, substantially as set forth.

5. In a conveyor, the combination with a chain formed of articulated links, certain of which are provided with wings which are arranged in a plane above that of the links, of antifriction-wheels and wheel-carriers therefor supported upon said wings and extending across the links, whereby the wheel-carriers are supported in such position as not to interfere with the teeth of the driving or sprocket wheels, substantially as set forth.

6. In a conveyor, the combination with a chain formed of articulated links having side bars, certain of which are provided with wings which are arranged in a plane above that of the links, of antifriction-wheels for supporting the chain and carriers for the said wheels secured to the said wings, the said carriers being formed with depending bracket-arms carrying axles for the wheels, substantially as set forth.

7. In a conveyor, the combination with a chain-link having wings, a supporting-wheel, and a carrier for the wheel, having an attaching-plate adapted to be secured to the said wings, the said plate being formed with a hole *c* and a slot *d* for the passage of the attaching means, whereby the carrier is adapted for use with links of different sizes, substantially as set forth.

8. In a conveyor, the combination with a chain-link formed with wings, of an antifriction supporting-wheel, and a carrier for the wheel having a plate adapted to rest upon and be secured to the said wings, the carrier being provided with a bracket and axle for the wheel, and also with flanges which engage with the opposite sides of one of the wings, substantially as set forth.

9. In a conveyor, the combination with a chain-link having opposite side bars formed with wings, a carrier-wheel arranged to one side of the chain-link, and a support or carrier for the wheel secured to the wings of both of the side bars of the link, whereby the wheel is supported from both sides of the chain, substantially as set forth.

10. In a conveyor, the combination with a chain formed of articulated links, certain of which are formed with wings, of antifriction supporting or bearing wheels for the chain adapted to lie outside of the edge of the chain, reversible carriers for the wheels adapted to rest upon and be supported by the wings of the chain-links, and means for securing the said wheel-carriers to the wings of the chain-links, substantially as set forth.

11. In a conveyor, the combination of a plurality of parallel lines of chain formed of articulated links, cross-pieces connecting the lines of chain, and rollers or wheels arranged in the transverse planes of the said connecting cross-pieces, and outside of the edges of the lines of chain, substantially as set forth.

12. In a conveyor, the combination of a plurality of lines of chain formed of articulated links having side bars, certain of the side bars of the links being provided with wings, cross-pieces connecting the lines of chain and supported upon the said wings, supporting-wheels for the chains and carriers for the wheels also supported by the said wings, substantially as set forth.

13. A conveyor comprising a line of drive-chain, and parallel lines of supporting-chains and cross-pieces secured to the said line of chain, substantially as set forth.

14. A conveyor, comprising a line of drive-chain, lines of supporting-chains parallel thereto, cross-pieces uniting the said lines of chain, and supporting-wheels carried by the chain in line with the cross-pieces

and intermediate the joints or articulating parts of the chains, substantially as set forth.

700,848. OPERATING AND LATCH-RELEASING MECHANISM FOR SLIDING DOOR. WILLOW S. LINCOLN, Worcester, Mass. Filed Feb. 27, 1901. Serial No. 68,997. (No model.)

Claim.—1. In an operating and latch-releasing mechanism for sliding doors, the combination of an operating-handle pivotally mounted upon the sliding door, a sliding cam-piece or latch-releaser mounted in the sliding door and connected to be moved by the operating-handle, and a latch pivotally mounted in the door-casing, said parts being arranged so that when the operating-handle is pulled to open the door, the releaser will first disengage the latch, after which the door may be drawn open, substantially as described.

2. In an operating and latch-releasing mechanism for sliding doors, the combination of a latch-cock mounted in the door, a sliding inclined-coded latch-releaser or bolt, two operating-handles pivotally mounted on opposite sides of the sliding door and connected to move the latch-releaser, and a latch pivotally mounted in the door-casing in position to engage the latch-cock, said parts being arranged so that when either operating-handle is pulled to open the door, the releaser will first disengage the latch from its cock, after which the door may be drawn open, substantially as described.

3. In an operating and latch-releasing mechanism for sliding doors, the combination of a latch-cock-piece mortised into a sliding door, and having a face-plate for receiving screws to hold the same in place, a sliding latch-releaser mounted in the latch-cock-piece, operating-handles pivoted in brackets upon opposite sides of the door and having inwardly-projecting fingers engaging a notch in the latch-releaser, and a gravity-latch mounted in a pivot-place which is mortised into the door-casing and which is provided with a face-plate for receiving the screws for holding the same in place, said parts being arranged so that when either operating-handle is pulled to open the door, the releaser will first disengage the latch, after which the door may be drawn open, substantially as described.

700,844. BOTTLE-STOPPER. GEORGE LAFFMANN, Brooklyn, N.Y. assignor to Charles L. Curtis, Brooklyn, N.Y. Filed Nov. 16, 1900. Serial No. 38,711. (No model.)

Claim.—1. In a bottle-stopper, the combination of a bottle having a circumferential rim or flange, a cap having a crown-piece and depending flange, transversely-aligning apertures in said flange, and a boy having two parallel arms, each of which arm is adapted to be passed transversely through two of said apertures, and beneath the said rim or flange of the bottle to bind the cap on the bottle, substantially as described.

2. In a bottle-stopper, the combination with the bottle having a circumferential rim or flange, a cap having a crown-piece and depending flange, a plurality of aligning apertures in said cap, and a boy, comprising two parallel arms, each of which is adapted to be passed transversely through two of said apertures and a resilient disk between the bottle and the crown-piece, substantially as described.

3. In a bottle-stopper, the combination with a cap having a circular and depending flange provided with aligned and tangentially-disposed apertures, a bottle-stopper having a circumferential rim or flange, and a boy having parallel arms or prongs, each arm or prong extending tangentially through the apertures and under said rim.

4. As a new article of manufacture, a bottle-stopper comprising a cap-like cap having a crown-piece and a depending flange with a plurality of aligned apertures formed therein on each side, and a boy having parallel arms or prongs each of which passes through two of the aligned apertures, as set forth.

5. As a new article of manufacture, a bottle-stopper comprising a

cap-like cap having a crown-piece and depending flange, a plurality of transversely-extending and closing apertures formed in the flange and diametrically disposed relatively to each other, and a key comprising two parallel arms or prongs and a connecting cross-bar, each prong being adapted to be passed through two of said closing apertures, as set forth.

6. A bottle-stopper comprising a cap-like cap, having a crown and a depending flange, and holes formed in the flange diametrically disposed relative to each other, an outwardly-extending flange or channel formed in the flange between each set of apertures, and a key comprising parallel arms or prongs and a connecting cross-bar adapted to pass through said closing apertures, and lie in said flange, as set forth.

7. The combination with a bottle, of a flanged cap for the mouth thereof, the neck of the bottle and the flange of the cap being provided with matching grooves, a wire having parallel arms located intermediate between the neck and cap and locking the cap to the bottle by lying partly in each groove, and an opening through the flange of the cap into its groove, through which the wire can be withdrawn from its locking position, with both grooves, substantially as described.

700,845. TUG-FASTENER. JAMES L. LEECH, Inventor. Filed Oct. 4, 1901. Serial No. 77,732. (No model.)

Claim.—The combination with a whistle, the end of which is grooved longitudinally, of a ferrule or thimble arranged thereon, said ferrule or thimble having an opening adapted to align with the groove in the whistle, bearing-recesses produced adjacent to the end of the said opening, a lag arranged at the end of the opening, the pivot passing through the lag and resting in the bearing-recesses, a spring secured within the ferrule, the free end bearing against the flattened end of the lag, the upper face of the ferrule or thimble being forced upwardly to accommodate the free end of the spring and serve as a stop-shoulder for the lag, substantially as above and described.

700,846. ELECTRIC RAIL-BOND. WILLIAM J. LEO and JAMES R. BOLGER, Inventors. Filed Feb. 26, 1902. Serial No. 91,002. (No model.)

Claim.—1. In a device of the class described the combination with rails, of a fish-plate provided at its lower face with a longitudinal groove, an electric rail-bond consisting of a thin copper plate seated in the groove and entirely filling the same throughout its entire length and interposed between the rails and the fish-plate, said fish-plate forming a casing or housing for the electric rail-bond and supporting the same at the upper and lower edges thereof throughout the entire length of the same, substantially as described.

2. In a device of the class described, the combination of the rails provided at their ends with perforations arranged in pairs, fish-plates arranged at opposite sides of the rails and provided with elongated openings arranged in pairs, an electric rail-bond consisting of a thin copper plate provided at its ends with elongated openings registering with the end perforations of the rails and with the inner openings of the fish-plates, said electric-rail-bond being snugly seated and secured within a groove of the inner face of one of the fish-plates and entirely filling the same throughout its entire length, whereby it forms a rigid structure with the said fish-plates and is supported and protected by the same, and the bonding devices, passing through the said perforations and openings, substantially as described.

700,847. COTTON-GIN. ROBERT B. LAMBERT, STUART, TEX. Filed Oct. 2, 1901. Serial No. 51,912. (No model.)

Claim.—1. In a cotton-gin, an off-shoot chute curved in a vertical plane and of less cross-section at its intake than at its outlet end, an adjustable approximately U-shaped metal-board having one member projecting into the intake end of the chute, and means for holding the metal-board at the desired adjustment.

2. In a cotton-gin, the combination with the saw, of an off-shoot chute having its lower side terminating short of the saw, an approximately U-shaped metal-board carried by the said lower side and disposed below the axis of the saw, and having one member projecting into the intake end of the chute, and a blast-mechanism having an elongated discharge-mouth opening toward the chute.

3. In a cotton-gin, the combination with the saw and the condenser, of an off-shoot chute approximately horn-shaped in side elevation, the smaller end constituting the intake and being disposed adjacent to the saw, and the larger end constituting the discharge and communicating with the condenser, the lower side of the intake terminating short of the saw presenting thereby a passage to permit escape of seeds and dirt, an adjustable approximately U-shaped metal-board carried by the lower side of the intake and having one member projecting into the chute, and blast-mechanism disposed above the saw and discharging in the direction of the chute.

4. In a cotton-gin, an off-shoot chute curved in a vertical plane and of less cross-section at its intake than at its outlet end, a bracket carried by the intake end of the chute, an approximately U-shaped metal-board having one member projecting into the intake end of the chute and the other in engagement with the bracket, and means carried by the bracket for holding the metal-board at the desired adjustment.

5. In a cotton-gin, the combination with the saw, of an off-shoot chute having its lower side terminating short thereof, having thereby an open space to permit escape of seeds and dirt, an approximately U-shaped metal-board carried by the lower end of the chute and having one member projecting into the intake end thereof, a condenser communicating with the chute, blast-mechanism, a head disposed adjacent to the saw and communicating with the blast-mechanism, a headboard partially enclosing the discharge end of the head, and a blast-mechanism carried to the head-board and to the lower side of the head and discharging toward the chute.

6. In a cotton-gin, the combination with the saw, of an off-shoot chute, an approximately U-shaped metal-board carried by the chute and having one member projecting into the intake end thereof, a condenser communicating with the chute, blast-mechanism, a head disposed adjacent to the saw and communicating with the blast-mechanism, a blast-mechanism carried by the head, and pressure-equalizing mechanism connected with the blast-mechanism.

7. In a cotton-gin, an off-shoot chute, an approximately U-shaped metal-board having one member projecting into the intake end thereof, blast-mechanism discharging in the direction of the chute, and pressure-equalizing mechanism connected with the blast-mechanism.

700,848. COLOR-READING WOOD. SAMUEL LYON, Hamburg, Germany. Filed Feb. 11, 1902. Serial No. 92,495. (No specimens.)

Claim.—1. The herein-described die for pyrographic decoration in which parts are projected so as to contact with the material sufficiently to char parts of the design, and the parts of the die immediately adjacent

to said charring parts are arranged at angles that vary according to the surfaces bounding the charred portions of the contemplated design are intended to contract or expand as to light and shade with said charred portions, substantially as and for the purpose set forth.

2. The herein-described die for pyrographic decoration in which parts are projected so as to contact with the material sufficiently to char parts of the design, the parts of the die immediately adjacent to said charring parts are arranged at angles that vary according to the surfaces bounding the charred portions of the contemplated design are intended to contract or to expand as to light and shade with said charred and each portion of the die as are intended to produce areas of uniform tint of any shade, being maintained at a uniform distance from the surface acted upon, substantially as and for the purpose set forth.

700,849. BRAKE AND HILL FOR VEHICLES. GEORGE E. MADSEN, Hayward, Cal. Filed Nov. 4, 1901. Serial No. 91,002. (No model.)

Claim.—1. The combination in a bicycle-brake of clamps, means for securing them to the bicycle-head, a plate interposed with relation to said clamps, and having a furled outer end, a roller journaled between said furled end and including a central core, an elastic sleeve surrounding the core and metal bands upon the ends of the core, said sleeve having the portion between the bands of less diameter than said bands, and provided with a spiral wrapping of cord, a pressure-plate having ends adapted to press upon the metal end bands of the roller in opposition to the pressure of the central portion of the tire, a spring acting upon said plate to hold the sleeve normally out of contact with the roller, a guided rod connected to the plate, and extending upwardly, and a brake-lever for actuating the rod.

2. The combination in a bicycle-brake of a clamp, means by which it is secured to the bicycle-head, a plate pivotally mounted at one end and having its other end furled, a roller journaled between said furled end and including a core having a reduced central portion and an elastic sleeve fitting said reduced portion, and metal bands on the ends of the core, means whereby the roller is pressed into contact with the tire, a pressure-plate to engage said end bands of the roller and means for actuating said pressure-plate, a bell carried by the first-mentioned plate, a hammer interposed to the plate, and a pin carried by the roller and engaging said arm, and means for moving the hammer to act upon the bell.

3. The combination in a bicycle-brake of a clamp, means by which it is secured to the bicycle-head, a plate pivotally mounted at one end and having its opposite end furled, a roller mounted in the furled end and of the plate having insulate ends and an elastic intermediate portion to be forced

into contact with the tire, a furled pressure-plate having ends to engage the insulate ends of the roller and means for actuating the pressure-plate to press the elastic portion of the roller into contact with the tire, a bell and its actuating-hammer, and a pin carried by the roller for actuating the hammer substantially simultaneously with the application of the brake-lever to the tire.

4. In a bicycle-brake the combination of a plate pivotally mounted at one end and having a furled opposite end and a roller mounted in said furled end and comprising a core the central portion of which is of less diameter than the ends, metal bands upon said ends and an elastic sleeve upon the reduced central portion, said sleeve wound transversely around said sleeve between said ends and forming the bearing-surfaces of the roller, a pressure-plate interposed at one end and carrying a shoe at the other end, to engage said metal bands, and a means for depressing the plate to cause it to force the curved surface of the roller into contact with the wheel-tire.

5. The combination in a bicycle-brake of a clamp, two levers, one above the other and independently movable, and a single axis about which both levers are movable, a roller journaled in the lower lever and adapted to press upon the wheel of the machine, said roller having a core with reduced central portion and metal bands upon the ends, and a yielding surface upon the reduced portion, a shoe carried by the upper lever, and adapted to press upon the end bands of the roller, an interposed spring by which the levers are normally separated, a rod connected with the upper lever and means for applying pressure whereby the roller is first brought into contact with the wheel, and the shoe subsequently caused to press upon the roller.

6. The combination with a bicycle of a clamp, superposed levers fulcrumed thereto, a roller journaled in the lower lever and adapted to contact with the wheel, said roller including a central core with a reduced portion between its ends and metal bands upon said ends, and a yielding surface on said reduced portion, a shoe carried by the upper lever above the roller and adapted to press on said bands, a spring by which the levers are normally separated, a bell and a furled hammer-lever, a pin upon the roller contacting with said lever, and a means for applying pressure through the upper lever whereby the roller is first placed in contact with the wheel to sound the bell, and a further pressure forces the shoe into contact with the roller.

700,850. BICYCLE-BRAKE. ALBERT HAIN, Fowlesham, Cal. Filed Jan. 6, 1902. Serial No. 91,002. (No model.)

Claim.—1. The combination in a bicycle-brake of a rim interposed out of and interior to the felly of the wheel, lag and belt connections between the rim and felly and securing one to the other, a brake-shoe opposing upwardly against the rim and engaging the latter at right angles with the axis of the machine, and means for operating the brake-shoe.

2. The combination with a bicycle-wheel of lugs fixed at intervals within the wheel-felly and having channels upon the exterior edge, a rim fitting said channels and bolted thereto, having its inner periphery of smaller diameter and clear of the lugs and felly, a brake-shoe curved to fit said inner periphery having guide-lugs upon opposite sides, a guided

slidable rod connected with the shoe and connections between said rod and a hand-lever by which the shoe may be forced into contact with the interior of the rim.

3. The combination with a bicycle-wheel of a rim, legs fixed to the interior of the wheel-hub by which the rim is supported within the hub and at one side of the wheel-spokes with the inner periphery independent thereof, a brake-shoe curved to fit said periphery having guides upon each side, a rod guided and slidable upon a wheel-frame having arms by which it is united with the brake-shoe, a bell-crank lever, a cord connecting it with the slidable rod, a hand-lever at the bicycle-hand and a cord connecting it with the bell-crank lever whereby the brake-shoe may be caused to press against the interior of the smaller rim and at right angles with the wheel-shaft.

700,851. STOPPER FOR MILLER-TUBES OR HOLLOW SHAFT.
ING. HENRY T. HANSEN, Chicago, Ill. Filed Aug. 14, 1901. Serial No. 73,015. (No model.)

Claim.—1. The combination with a hollow metallic member, of a stopper therein comprising an expandable head formed in sections, compressible material covering the joints between adjoining sections of the head, and means for expanding the head and the compressible material.

2. A stopper for boiler-tubes or hollow shafting, comprising an expandable head formed in sections and having an opening extending longitudinally therethrough, a wedge member within the opening, a clamp or stem carried by the wedge projecting beyond the head, a clamping member upon the clamp, compressible material intermediate said clamping member and the head, and means upon the clamp for drawing the wedge and clamp together to expand the head and the compressible material.

3. A stopper for metallic tubing comprising an expandable head formed in sections and having a tapering opening extending longitudinally therethrough, a wedge within the opening carrying a clamp or stem threaded at its free end, a clamping-plate loosely secured upon the clamp, a ring of compressible material intermediate the plate and the head, and a nut engaging the clamp and bearing against the plate.

4. A stopper for boiler-tubing or hollow shafting, comprising an expandable head formed in sections and having a tapering conical opening extending centrally and longitudinally therethrough, a conical wedge fitting within the opening, said wedge contacting with the walls of the opening throughout the entire length of the latter and having a flaring section at its outer end abutting against the edges of the head-sections, a clamp or stem integral with the wedge and projecting beyond the head, a conical clamping-plate loosely secured upon the clamp, a ring of compressible material intermediate the head and the plate and a nut threaded upon the free end of the stem adapted to bear against the plate.

700,852. REVERSIBLE ENVELOP OR WRAPPER. WILLIAM MARTIN, Kansas City, Mo. Filed June 22, 1901. Serial No. 68,561. (No model.)

Claim.—1. In a reversible envelop or wrapper comprising four flaps, three of said flaps having a perforation in each, an opening in the flap not so perforated, and a flexible metallic fastener secured to said flap and projecting into said opening when unrolled, said fastener comprising a middle foot portion *B'* and a pair of tongues *B*, and being so located with respect to the perforations in the other flaps that said tongues may be inserted through all of said perforations, when the envelop is folded in either direction, substantially as described.

2. A reversible envelop or wrapper comprising three flaps *A*, *B*, *C* provided with perforations *7*, a flap *D*, a flap *E* cut therefrom and folded back upon said flap *D*, leaving an opening *8*, and a flexible metallic fastener comprising a middle foot portion *B'* and a pair of tongues *B* projecting through the fold of said flap *E*, the foot portion *B'* lying between said flaps *D* and *E*, substantially as described.

700,853.

700,853. CRANE. GEORGE C. HATFIELD, San Francisco, Wash. Filed Mar. 11, 1900. Serial No. 97,397. (No model.)

Claim.—1. The combination of a base-frame, consisting of side rails 1, and cross-beams 2; a braced central post 3, having about two-thirds of the way from its base, a shoulder 4, and resting on said shoulder, a collar 4'; the balance of said post terminating in a cylindrical bearing 5; a collar 6, encircling said cylindrical bearing 5, and resting on said collar just named; arm-cockets 7, extending upwardly and at an angle of about forty-five degrees from said post; arms 8, secured in said cockets, and extending upwardly at the same angle; a swinging beam 9, secured horizontally to the upper ends of said arms 8, and at right angles to said post; a bolt 11, passing through a perforation 10, in the beam 9, and into the upper end of the cylindrical bearing 5; a lock 17, secured to one corner of the beam; a cable, one end secured to the tongue part 21, of said lock, and the other to one end of the beam; a hoisting-cable 24, having a double-throw secured to its free end; said cable passing under a pulley 13, secured to one end of the beam 9, and over another pulley 12, secured in the other end of said beam, and thence downwardly, and adapted to be secured to a sling or grapple-hook, and an operating-cable having one end secured to the hoisting-cable, near the double-throw, the other end secured to the upper end of the tongue part 21, of the lock, substantially as shown and described and for the purposes set forth.

2. The combination of a base-frame; a vertical central braced post, having some distance from its lower end, a shoulder; a collar bearing resting on said shoulder, the balance of said post terminating in a cylindrical bearing; a collar journaled on said cylindrical bearing and resting on said collar bearing; arms extending upwardly at right angles from said collar; a swinging beam secured horizontally to the upper ends of said arms; a bolt passing down through the center of said beam into the top of said cylindrical bearing; a lock secured to one corner of said beam; a cable, one end secured to the tongue part of said lock and the other to

one end of said swinging beam; a hoisting-cable, having a double-throw secured to one end, said cable passing under a pulley secured to the base-frame, passing thence up over pulley secured to the under face of said cross-beam, and thence downwardly, and adapted to be secured to a sling or grapple-hook, and an operating-cable, one end secured to the hoisting-cable and the other to the upper end of the tongue part of the lock, substantially as shown and described and for the purposes set forth.

700,854. HANDLE. WILLIAM E. HAYTHAM, Lancaster, Mass. Filed Mar. 2, 1900. Serial No. 68,440. (No model.)

Claim.—1. A handle for the purpose described having a bore extending therethrough, a spring located within said handle and adapted to be connected to the valve chain or cord, means for positively preventing the withdrawal of the spring from the handle in one direction, said spring exerting its energy to prevent its movement through the handle in the opposite direction, substantially as set forth.

2. A hollow handle for the purpose described, a spring located within the hollow handle and provided at one end with a spring-arm adapted to bear against the interior wall of the handle and limit the movement of the spring in one direction and afford means for the connection of the valve cord or chain, said spring being provided at its other end with a head to limit the movement of the spring in the opposite direction and thereby prevent the withdrawal of said spring through said handle when the handle is grasped and pulled down, substantially as set forth.

700,855. COMBINED BOX OR CHEST AND TABLE. FRED L. KIRCHMILL, New York, N. Y. Filed Aug. 14, 1901. Serial No. 73,100. (No model.)

Claim.—1. In a device of the character described, the combination of a box-body having corner-openings, a cover therefor having corner-cockets, and standards insertible symmetrically through said openings and into said cockets to support the cover above the box-body, the lower ends of said standards having nuts to also hold the box-body at an elevation above the surface on which the standards rest, substantially as set forth.

2. In a device of the character described, the combination of a box-body having corner-openings, a cover therefor, formed with corresponding cockets, and standards adapted to be inserted upward through said openings and to be fitted at their upper ends in said cockets to support the cover at an elevation above the box-body, said standards being provided at their lower ends with shoulders for the body to rest upon, substantially as specified.

3. In a device of the character described, the combination of a box-body having corner-openings, wear-plates reinforcing said openings, upturned brackets above the openings, a cover therefor, formed with corresponding cockets, wear-plates reinforcing and closing the cockets at their inner ends, and standards adapted to be inserted upward through said openings, and brackets, and to be fitted at their upper ends in said cockets to support the cover at an elevation above the box-body, said standards being provided at their lower ends with shoulders for the body to rest upon, substantially as specified.

4. In a device of the character described, the combination of a box-body having corner-cockets, a cover having corresponding cockets, removable standards adapted to be fitted in said cockets to support the cover at an elevation above the box-body, and upturned brackets on said box-body adapted to receive and support said standards, substantially as in the manner set forth.

5. In a device of the character described, the combination of a box-body having corner-cockets, standards adapted to be removably fitted at

their lower ends in said cockets, and a reversible cover adapted to be removably supported upon said standards in a reversed position and having cockets to receive the upper ends of said standards, substantially as described.

6. In a device of the character described, the combination of a box-body provided with corner-cockets and bolt-openings, a removable reversible cover provided with corresponding cockets and bolt-openings, removable standards adapted to support the cover in reversed position above the box-body and to be fitted in said cockets, and bolts adapted to be passed through said bolt-openings to secure the cover to close the box-body upon the removal of the standards, substantially as set forth.

700,856. COLLAPSIBLE CAMP-STOVE. FRED L. KIRCHMILL, New York, N. Y. Filed Aug. 14, 1901. Serial No. 73,100. (No model.)

Claim.—1. In a collapsible camp-stove, a stove-body formed of side and end plates and a top, bolts having their threaded shanks projecting loosely through openings in the side and end plates, a curved plate-spring secured intermediate of its ends to the end walls between said openings and carrying said bolts, and nuts engaging the shanks of the bolts and holding the ends of the plate-spring under tension whereby, upon the disengagement of the nuts, the said ends of the spring will be freed and retract the bolts, substantially as described.

2. In a collapsible camp-stove, a stove-body formed of side and end plates and a top, bolts having their threaded shanks projecting loosely through openings in the side and end plates, springs fixed to the end walls and engaging the bolts, and nuts upon the bolts and holding the springs under tension whereby, upon the disengagement of said nuts, the springs will retract the bolts, substantially as specified.

3. In a collapsible camp-stove, a side wall, an end wall provided with an offsetting flange, said side wall and flange being provided with registering openings, a spring-plate centrally secured to said flange, bolts carried by the ends of said spring-plate and adapted to project through said openings, and nuts to engage the bolts and hold the ends of the springs under tension whereby, upon the disengagement of the nuts, the said ends of the springs will be freed and retract the bolts, substantially as set forth.

4. In a camp-stove, a stove-body comprising side walls provided with angle-braces, and walls adapted to rest against said angle-braces, and having angle-braces extending around their edges, means for connecting the side and end walls, and a top formed of sections having angle-iron flanges which fit in slots in the side walls and rest upon the flanges on the end walls, substantially as described.

5. In a collapsible camp-stove, detachable side and end walls, the side walls being provided with slots and the end walls with offsetting flanges, and a top having a flange to engage the slots and to rest upon the flanges of the end walls, substantially as described.

6. In a camp-stove, a stove-body provided with draft-openings, doors for closing said openings, a fire-interchangeable to cooperate with either draft-opening, and an oven adapted to be supported by the fire, substantially as described.

7. In a camp-stove, a stove-body having draft-openings formed in its opposite end walls, and a slidable fire to cooperate with either of said draft-openings, substantially as described.

8. In a camp-stove, a stove-body having a draft-opening, a fire

adapted to cooperate therewith, a supporting-plate to rest upon the flange, a drum supported by said plate, and an oven in said drum, substantially as described.

9. In a camp-stove, a stove-body having a draft-opening, a flue adapted to cooperate therewith, said flue being removable and foldable, a plate supported by the flue and having a smoke-passage, a drum or casing carried by said plate, and an oven within the casing, substantially as described.

10. A collapsible camp-stove comprising side and end walls and a top, said parts being detachably connected and the side walls provided with draft-openings, a flue interchangeable to cooperate with either draft-opening, a supporting-plate to rest upon the flue, a drum adapted to be supported by the plate, and an oven in said drum, substantially as and for the purpose specified.

700,857. YOKES AND DRAFT-BAR FOR COUPLINGS. ROBERT MORRIS, La Crosse, Wis. Filed Feb. 10, 1902. Serial No. 63,366. (No model.)

Claim.—1. A draft-bar and cooperating yoke or stirrup connected by dovetailed engagements which receive draft strain and prevent the prongs of said yoke from spreading, substantially as described.

2. The combination with a draft-bar having transversely-extended and tapered dovetailed ends, of a draft-yoke having transversely-extended and tapered dovetailed ribs fitting said ends, and a bolt passed through said draft-bar and the prongs of said yoke for holding said parts together, substantially as described.

3. The combination with a draft-bar having transversely-extended and tapered dovetailed ends, a draft-yoke having transversely-extended and tapered dovetailed ribs fitting said ends, and a tapered bolt passed through perforations in said draft-bar and in the prongs of said yoke and tending to force said ribs tightly into said ends, substantially as described.

4. The combination with the draft-bar 1 having the tapered transversely-extended dovetailed ends 3 and vertical perforations 8 of the yoke 4 having the perforations 7 and provided with the tapered dovetailed ribs 5 which fit in said ends 3, and the tapered bolt 6 passed through said perforations 7 and 8 and tending to force said ribs 5 tightly into said ends 3, substantially as described.

700,858. LOCK FOR MILK-RECEPTACLE. FRANK HOLLER, Philadelphia, Pa. Filed Sept. 24, 1901. Serial No. 76,368. (No model.)

Claim.—1. In a lock for milk-receptacles, a lock-casing consisting of two members arranged parallel with one another, a space between said members, said space being open at each end and one side, the other side being closed by the connection between the two members, a spring-catch arranged in the space between the two members, the said lock-casing adapted to be so placed upon the door or door-jamb that the open side

of the lock will be closed when the door is closed, a loop secured to the milk-receptacle, said loop adapted to be inserted from below in the space between the two members and be locked in place by the spring-catch, substantially as and for the purpose specified.

2. In a device of the character described, a lock consisting of two members lying parallel with one another, a space between said members, said space being open at the top, bottom and one side and closed at the other side by the connection between the two members, said lock adapted to be secured to the door or door-jamb in such a position that the open side of the lock will be closed when the door is closed, a spring secured to the inner face of the outer member, said spring turned back upon itself at each end so as to form spring-catches, said spring-catches being normally in spring contact with the inner face of the inner member, a loop secured to the milk-receptacle and extending upward therefrom, said loop adapted to be inserted between the two members of the lock and forced upward past the spring-catches for the purpose of locking the receptacle in place, substantially as and for the purpose set forth.

3. In a lock for milk-receptacles, a lock-casing consisting of two members arranged parallel with one another, a space between said members, said members being connected together along one side, the lock adapted to be so placed upon the door or door-jamb that the door when closed will close the open side of the space between the two members, a strip of spring metal secured at the center to the inner face of one of the members, the ends of the spring-strip being bent back upon itself, the said ends being in spring contact with the inner face of the opposite member to which the strip is secured, substantially as and for the purpose specified.

700,859. WAREHOUSE. JAMES D. McFARLANE, JR., San Francisco, Cal., assignor of one-half to John Bruckman, San Francisco, Cal. Filed Oct. 23, 1901. Serial No. 59,551. (No model.)

Claim.—1. The combination in a warehouse of a large hall having an enlarged head, and a jaw consisting of two independently-revoluble jaw members mounted in said head.

2. The combination in a warehouse of a handle, and a revoluble jaw carried thereby, said jaw consisting of a plurality of slotted disk jaws independently revoluble in relation to each other.

3. The combination in a warehouse of a handle, a revoluble jaw mounted thereon, an opening in said jaw for the admission of the pipe or other article to be engaged, and an independently-revoluble jaw for contracting said opening to engage articles of various sizes.

4. The combination in a warehouse of a handle, a revoluble jaw mounted thereon and adapted to be actuated by the collision of the handle, said jaw consisting of independently-revoluble members and jaw-openings in these members which are adapted to contract to admit an article to be engaged.

5. The combination in a warehouse of a handle having an enlarged head, a circular opening in said head, a circular jaw mounted in said opening, said jaw consisting of two members, one carried by and rotatable independently of the other, and means by which said members may be revolved in unison.

6. The combination in a warehouse of a handle having an enlarged head, a circular revoluble jaw set into said head, said jaw consisting of members rotatable independently of each other, jaw-openings in said

members adapted to contract, and means for rotating one of said members in contact with said jaw-opening.

7. The combination in a warehouse of a handle having a circular opening, revoluble jaw members mounted in said opening, one of said members adapted to be driven by the collision of the handle, the other of said members carried by but rotatable independently of the other member, and means for locking said members so that each independent movement is prevented.

700,860. MANUFACTURE OF STEAM-GENERATOR SHELLS. CYLINDERS, &c. RALPHUS F. MOTTEN, Babbitt, England. Filed June 19, 1906. Serial No. 54,899. (No model.)

Claim.—1. The process of manufacturing seamless metal cylinders of large size, and of the diameter and also thickness required, consisting of first producing a perforate seamless blank or billet from which the cylinder is to be made, then rolling said blank or billet circumferentially and increasing its external diameter until it is of larger size than the cylinder required, and then reducing this excessive size by rolling it circumferentially at points all around simultaneously from one end to the other, while it is being revolved axially.

2. The process of manufacturing seamless metal cylinders of large size, and of the diameter and also thickness required, consisting of first producing a perforate seamless blank or billet from which the cylinder is to be made, then rolling said blank or billet until it is of larger diameter than the finished cylinder but of the required thickness, and then subsequently reducing the diameter by rolling it externally at points all around, in substantially the same transverse plane of said cylinder, from one end to the other, while it is being revolved axially whereby the excess of metal caused by the reduction is transferred into a longitudinal extension.

700,861. MACHINE FOR MAKING SEAMLESS TUBES OR ROLL-LOW ARTICLES. RALPHUS F. MOTTEN, Babbitt, England. Filed Aug. 14, 1904. Serial No. 71,022. (No model.)

Claim.—1. In a machine for rolling hollow cylinders circumferentially, and internally and externally, the combination of a large horizontal lower driven roller; an upper small non-driven loose roller directly above the lower roller, for rolling on the internal surface; vertical positive adjusting means, for adjusting the top roller positively and keeping it parallel, in relation to the lower roller; external side supporting-rollers on either side, for supporting the sides of the hollow cylinder, connected together and adapted to be moved simultaneously in opposite upward directions away from the vertical plane of the machine, in the rolling operation, whereby the side supporting-rollers support the body at parts near the horizontal diametrical plane constantly, as this plane shifts during the increase of diameter of the body; substantially as set forth.

2. In a machine for rolling hollow cylinders circumferentially, and inter-

nally and externally, the combination of a large horizontal lower driven roller; an upper small non-driven loose roller directly above the lower roller, for rolling on the internal surface; vertical positive adjusting means, for adjusting the top roller positively and keeping it parallel, in relation to the lower roller; external side supporting-rollers on either side, for supporting the sides of the hollow cylinder, connected together and adapted to be moved simultaneously in opposite upward directions away from the vertical plane of the machine, in the rolling operation, whereby the cylinder is supported at either side at parts near the horizontal diametrical plane; and means for tilting the axes of said side-supporting rollers; substantially as set forth.

3. In a machine for rolling hollow cylinders circumferentially, and internally and externally, the combination of a large horizontal lower driven roller; an upper small non-driven loose roller directly above the lower roller, for rolling on the internal surface; vertical positive adjusting means, for adjusting the top roller positively and keeping it parallel, in relation to the lower roller; external side supporting-rollers on either side, for supporting the sides of the hollow cylinder, connected together and adapted to be moved simultaneously in opposite upward directions away from the vertical plane of the machine, in the rolling operation, whereby the cylinder is supported at either side; and means for tilting the axes of said side-supporting rollers; substantially as set forth.

4. A machine for rolling cylinders circumferentially, comprising rollers adapted to roll on the interior and exterior surface of the said cylinder, having their axes parallel to one another, one of the said rollers being adjustable in relation to the other, and guide or supporting rollers for supporting the body externally, and means for inclining the axes of the guiding-rollers so as to be inclined in relation to the axes of the rolling-rollers; for the purposes set forth.

5. In a machine for rolling hollow cylinders circumferentially, by peripheral internal and external rolling, supporting-rollers *f*, means whereby said supporting-rollers are caused to act on the exterior of the body being rolled, and to move in an oblique direction outward and away from the rolling-rollers, whereby each body is supported on its opposite sides near the axial plane which lies at right angles to the plane in which the axes of the rolling-rollers lie, as the body increases in diameter; substantially as described.

6. In a machine for rolling hollow cylinders circumferentially by internal and external peripheral rolling, internal and external rolling-rollers, means for causing the internal roller to be moved longitudinally through the base of the cylinder, and having a tool on the end of said internal roller which passes through the cylinder, adapted to act on the interior surface of the cylinder, when being passed through it; substantially as and for the purposes specified.

7. In a machine for rolling hollow cylinders by peripheral internal and external rolling, lower and upper rollers *a* & *b*, bearings or frames *c* & *d*, and bearings carried thereby, external supporting-rollers *f*, shafts *g* carrying the rollers *f*, and adjusting means connected with the shafts *g* by which the inclination of these shafts and rollers *f* are changed and set as required; substantially as and for the purposes set forth.

8. In a machine for rolling hollow cylinders, internal and external peripheral rolling-rollers, external side-supporting rollers, shafts carrying said supporting-rollers, and movable supports carrying bearings for said shafts and serving to vary the inclination of said shafts, substantially as described.

9. In combination with the large supporting-roller, the roller above the same, the side rollers, the shafts upon which said side rollers are supported and a swinging lever for supporting one end of the said shaft with means for operating the lever to change the inclination of the shaft.

10. In combination, the supporting-roller, a roller centrally arranged above the same, the side rollers to bear upon the outside of the tubes, arms carrying the side rollers, shafts for supporting said arms, said shafts being arranged to turn for adjusting the arms and rollers, swinging levers at one end of the shafts for supporting the same adjustably so that their inclination may be changed and means for turning the shafts to adjust the rollers, substantially as described.

700,862. ADJUSTABLE WINDOW-SCREEN. OTTO EHRMAN, West Berkeley, Cal. Filed Jan. 12, 1902. Serial No. 90,016. (No model.)

Claim.—1. An adjustable window-screen consisting of a spring-actuated screen-roll, means for attaching it to one side of a window-frame, means upon the opposite side of the frame by which the screening may be engaged and held in opposition to the spring, and laterally-adjustable bars connecting the bar at one side of the window-opening with the roller-support at the opposite side.

2. An adjustable window-screen, consisting of a casing, a spring-actuated screen-roll journaled therein, said casing adapted to be secured upon one side of the window-frame, means upon the opposite side of the frame by which the end of the screening may be engaged and held in opposition to the spring, and upper and lower folding bars connecting the bar at one side of the opening with the roller-casing at the opposite side.

3. In an adjustable window-screen the combination of a casing, a hollow roller having a central shaft projecting from one end and about which said roller is turnable, a slot in said roller a spring secured at one end to the shaft and the other end fixed in said slot, a cap through which the shaft passes, said cap fixed to and turnable in unison with the roller, perforations in the cap and shaft, a pin adapted to be passed through said perforations whereby the tube and shaft may be locked together, and the former prevented from turning, a flexible screening wound upon said roller, and bars pivotally connected to the casing and adapted to extend transversely across the window-opening, and a bar attached to the screening and with which the transverse bars are adapted to connect.

4. The combination in an adjustable window-screen of a casing, a spring-actuated screen-roller therein, means for attaching said casing to the side of a window-frame, a slot in said casing through which the screening is drawn, a bar exterior to the casing and to which the end of said screen is attached, means upon the opposite side of the window-frame by which said bar may be engaged and the screen held in opposition to the tension of the spring, and pivotally-mounted longitudinally-extensible bars adapted to connect the bar at one side of the window-opening with the roller-casing at the opposite side.

5. The combination of a flexible screening, a spring-actuated roller upon which said screening is carried, a movable support for said roller, said support adapted to be detachably secured to a window-frame, means upon the opposite side of said frame with which the end of said screening may be engaged, said means consisting of a bar having a flange projection thereon, and adjustable lateral guides connecting said bar and roller-support.

700,863. MACHINERY FOR CONVERTING MOTION. HENRY C. HENRY, Port Wayne, Ind. Filed Aug. 1, 1901. Serial No. 79,464. (No model.)

Claim.—1. In mechanism of the class described, a main frame shaped

to support the various parts; a movable frame so supported on the main frame that it may be moved in a vertical plane; and a plunger-rod secured to the said movable frame, in combination with a shaft journaled in the main frame; two cams secured to the said shaft in different planes; and projections on the movable frame, one engaged by the under side of one cam and the other engaged by the upper side of the other.

2. In mechanism of the class described, a main frame shaped to support the various parts; a movable frame so supported on the main frame that it may be moved in a vertical plane; and a plunger-rod secured to the said movable frame, in combination with a shaft journaled in the main frame; two cams secured to the said shaft in different planes; and rollers journaled on the movable frame, one engaged by the under side of one cam and the other engaged by the upper side of the other.

3. In mechanism of the class described, a main frame shaped to support the various parts; a movable frame so supported on the main frame that it may be moved in a vertical plane; and a plunger-rod secured to the said movable frame, in combination with a shaft journaled in the main frame; two cams secured to the said shaft in different planes; and projections on the movable frame, one engaged by the under side of one cam and the other engaged by the upper side of the other, the cams being so shaped as to give a comparatively slow up motion and a comparatively quick down motion of the movable frame.

4. In mechanism of the class described, a main frame shaped to support the various parts; a movable frame so supported on the main frame that it may be moved in a vertical plane; and a plunger-rod secured to the said movable frame, in combination with a shaft journaled in the main frame; two cams secured to the said shaft in different planes; and rollers journaled on the movable frame, one engaged by the under side of one cam and the other engaged by the upper side of the other, the cams being so shaped as to give a comparatively slow up motion and a comparatively quick down motion of the movable frame.

5. In mechanism of the class described, a main frame; a movable frame pivoted on the main frame; and a plunger-rod pivoted to the movable frame, in combination with a shaft journaled in the main frame; two cams secured to the said shaft in different planes; and projections on the movable frame, one engaged by the under side of one cam and the other engaged by the upper side of the other.

6. In mechanism of the class described, a main frame; a movable frame pivoted on the main frame; and a plunger-rod pivoted to the movable frame, in combination with a shaft journaled in the main frame; two cams secured to the said shaft in different planes; and projections on the movable frame, one engaged by the under side of one cam and the other engaged by the upper side of the other, the cams being so shaped as to give a comparatively slow up motion and a comparatively quick down motion of the movable frame.

7. In mechanism of the class described, a main frame; a movable frame pivoted on the main frame; and a plunger-rod pivoted to the movable frame, in combination with a shaft journaled in the main frame; two cams secured to the said shaft in different planes; and rollers journaled on the movable frame, one engaged by the under side of one cam and the other engaged by the upper side of the other.

8. In mechanism of the class described, a main frame shaped to support the various parts; a movable frame so supported on the main frame that it may be moved in a vertical plane; and a plunger-rod secured to the said movable frame, in combination with a shaft journaled in the main frame; two cams secured to the said shaft in different planes; and projections on the movable frame, one engaged by the under side of one cam and the other engaged by the upper side of the other; a gear-wheel fixed on the cam-shaft; a driving-shaft journaled on the main frame; and a pinion fixed on the driving-shaft and meshing with the said gear-wheel.

9. In mechanism of the class described, a main frame shaped to support the various parts; a movable frame so supported on the main frame that it may be reciprocated, in combination with a shaft journaled in the main frame; two cams secured to the said shaft in different planes; and projections on the movable frame engaged by the said cams to reciprocate the said frame.

10. In mechanism of the class described, a main frame; a movable frame adjustably pivoted on the said main frame, in combination with a shaft journaled in the main frame; two cams secured to the said shaft in different planes; and projections on the movable frame engaged by the said cams.

11. In mechanism of the class described, a main frame; and a movable frame so supported that it may be reciprocated, in combination with a shaft journaled in the main frame; and two cams secured to the shaft in different planes, the movable frame being adapted to be reciprocated by the said cams.

700,864. RETAILER BOOK-CRISTING. WILLIAM F. ECKHART and JOHN E. ECKHART, Nevada, Mo. Filed Jan. 2, 1902. Serial No. 94,396. (No model.)

Claim.—1. A ridge-roll provided with a hollow flange or gutter, in combination with a crest interlocked with the walls of the flange.

2. A ridge-roll provided with a longitudinally-disposed gutter terminating short of the ends thereof, and a crest having its lower portion interlocked with the walls of the gutter.

3. A ridge-roll provided in its top with a downward-extending gutter, in combination with a crest having its lower edge reduced in length and interlocked with the walls of the gutter.

4. A ridge-roll provided with a longitudinally-disposed gutter terminating short of the ends thereof, and a crest having its lower edge reduced in length to correspond with that of the gutter and interlocked therewith.

5. A ridge-roll provided with a longitudinally-disposed gutter terminating short of the ends thereof, and a transversely-corrugated crest having its lower edge reduced in length to correspond with that of the gutter and interlocked therewith.

700,865. SKEW-PROPELLER. CHARLES A. PARSONS, New-Castle-upon-Tyne, England. Filed Dec. 22, 1900. Serial No. 69,774. (No model.)

Claim.—1. A screw-propeller provided with blades constructed with a reduced pitch toward their tips, the reduction commencing from about one-half to two-thirds outward from the blade-root, substantially as described.

2. A screw-propeller having vanes secured to the propeller-hub behind the blades, substantially as described.

700,866. MACHINERY FOR PACKING MERCHANTS. BERNARD L. PATTERSON, Durham, N.C. Filed Feb. 26, 1902. Serial No. 99,199. (No model.)

Claim.—1. In an organized apparatus for the manufacture and filling of packages, the combination of printing mechanism adapted to print a continuous web or sheet; a cutter to cut a blank therefrom; scoring or indenting devices to mark the lines of folding; folding mechanism adapted to give form to the package and to close its end; a delivery device for removing the bag from the forming mechanism; a carrier to receive the same; means for charging the bag with a predetermined quantity of material; and mechanism for sealing the filled bag or package.

2. In a machine for making bags or packages, the combination of means for feeding a continuous web; a knife or cutter for covering a blank therefrom; folding devices for forming said blank into a bag or package, the same comprising fixed walls 24, 26, pattern-block or form 27, fixed end-folder 27, side-folders 32, 33, end-folders 54, 55 and 57, and mechanism for imparting motion to said folders; a carrier to receive the bags or packages; and a stripper for removing the bags or packages from the forming device and delivering them to the carrier.

3. In combination with mechanism adapted to fold and connect bag material into the form of bags or packages, an endless chain of package-holders each adapted to contain and completely surround one bag or package; means for causing a travel of the carrier-chain; and heating jets or nozzles located along the path of the carriers and serving to heat them as they pass.

4. In combination with a bag or package forming mechanism, an endless carrier-chain provided with cells or boxes each adapted to contain and completely surround one bag or package; a bed or table over which said cells or boxes pass; and a heating-pipe extending along the line of travel of the boxes and the bed and serving to heat the boxes and the bed or table.

5. In a machine for forming, filling and sealing bags or packages, the combination of bag or package folding and connecting mechanism; an endless chain of boxes each to receive one of said bags or packages; a table or bed over which said boxes move; a guard beneath which the boxes move; and means for heating the boxes, table and guard; whereby all the lines of joining or connecting of the bags or packages may be hot and dried.

6. In a machine for forming bags or packages, the combination of a mold or forming-chamber having walls 34 and 35, movable bottom 54, and fixed end-folder 47; form or pattern-block adapted to extend into said rim end of the forming-chamber; end-folders 54 and 55; side-folders 32 and 33, and mechanism substantially such as described for actuating the several folders.

7. In a mechanism for filling material into the form of a bag or package, the combination of walls 24 and 25, pattern-block or form 27, right side-folder 32; pivoted side-folder 33; and means for holding the folder 33 normally above the level of folder 32.

8. In combination with walls 24 and 25; form or pattern-block 27; sliding head 40 provided with folder 32; sliding head 40 provided with yielding folder 33; spring 50 for elevating the folder 32; and head or plunger for depressing said folder after the same has moved inward to lay the outer fold of the bag or package upon the inner one.

9. In a machine for forming bags or packages, the combination of a mold or forming-chamber; a support for a bag-blank above said chamber;

10. In combination with a forming-chamber and with a support for a bag or package blank; a paste-receptacle; a paste-roll carried thereby; a yielding support for the paste-receptacle serving to hold it and its roll normally away from the blank; a lever connected with said receptacle and serving to move the same toward the blank; and a form or pattern-block adapted to bear upon the blank and carry it into the forming-chamber, and also to act upon the lever of the paste-receptacle to move and hold said receptacle toward the blank until the movement of said form or block is nearly completed.

11. In combination with walls 84 and 85; folders 33 and 33; turn or pattern-block 57 provided with leg 46; lever 41; counterbalance 42; paste-receptacle 30; paste-roller 40; and lever 44 connected with and serving to depress the paste-receptacle.

12. In combination with a form or pattern-block and means for folding a blank about the same; a fixed guide; a head movable upon said guide, provided with an open fork; a movable and piece applied to the form or pattern-block; a rod carrying said and piece, extending through the form or pattern-block, and provided with a cross-pin; means for moving the sliding head along the guide; and means for elevating and lowering the pattern-block, and piece and rod to carry the pin of the latter into and out of engagement with the fork of the sliding head.

13. In combination with a forming-chamber; form or pattern-block 57; and piece 56; rod 50 provided with pin 60; sliding head 38 carrying the pattern-block; elevating link and lever 61 and 62; cam 64; guide 76; sliding head 77 provided with an open fork lever 78 connected with head 77; draw-rod 79; lever 89; and cam 92, all substantially as shown and described.

14. In a packing-machine, the combination of a bag-holder; a presser-head adapted to enter a bag or package within said holder; and a paste-roller or paste-applying device carried by said head and adapted to apply paste within the bag-mouth.

15. In combination with a bag or package holder as 84, a presser-head 108 containing a paste-chamber; and a paste-roller having one side extending into said chamber and the other protruding therefrom to deliver paste within the mouth of a bag in the act of pressing the material therein.

16. In combination with a bag or package holder; a printing mechanism adapted to print a continuous strip; a bed or table between said printing mechanism and the holder; and a presser-head adapted to act in conjunction with the edge of said table to cut or shear a sheet from the printed strip and to carry it into the bag or package.

17. In combination with a suitable bag-holder; levers 129 and 130 provided respectively with yielding folding-blades 123 and 123; toggle 131 connecting said levers; and a cam for straightening and breaking said toggle to actuate the blades.

18. In a packing-machine, the combination of a packer or chambered measuring-wheel; a cylindrical shell or hopper containing said wheel; a pinion carried by the shaft of said wheel; a pawl-and-ratchet connection between the wheel-chest and pinion; a rack for turning said pinion; a cam for actuating said rack; and an adjustable connection between the cam and rack, whereby the throw of the rack can be varied to determine the extent of rotation and consequent delivery of the wheel.

19. In combination with a measuring-wheel and means for rotating the same; a scale-pan beneath the wheel; a dribbling-roll; friction driving-gear for said roll; a dog or detent for holding the dribbling-roll out of action; a connection between the scale-pan and the detent whereby the descent of the latter is caused to throw the detent to locking position; and an arm actuated by the wheel-rotating mechanism and serving to withdraw the detent as the wheel completes its movement.

20. In combination with a measuring-wheel provided with pinions and having its shaft provided with a ratchet-wheel, a pinion loosely mounted upon said shaft and provided with a dog or pawl to engage said ratchet-wheel; a rack for imparting motion to said pinion; a radius-bar; a cam for moving said radius-bar; and a rod connecting the radius-bar and the rack and adjustably connected with the latter, whereby the throw of the rack may be varied to move one or more than one of the pinions of the measuring-wheel at will to the delivery or discharge opening, substantially as set forth.

21. In combination with the scale-pan provided with doors or gates and with operating-levers 154 therefor; radius-bars 155 and 157; connecting-rod 156; lifting-spring 158, and depressing-pin 159 carried by wheel or 144.

22. In combination with a wheel having measuring-chambers, a ratchet-wheel; a pawl-carrier; a pawl mounted upon said carrier; and

means for varying the throw of the pawl-carrier to cause the pawl to ride back over a greater or less number of teeth of the ratchet, and to advance the wheel in discharge a corresponding number of chambers, substantially as shown and described.

23. In combination with a rotary drum or wheel provided in its circumference with receiving chambers or pockets; a ratchet-wheel having a common axle with said drum and arranged to move in unison therewith; a pawl-carrier; a pawl movable with said carrier and adapted to engage the ratchet-wheel; a rack meshing with and serving to rotate said carrier-wheel; a lever for imparting motion to said rack; an adjustable connection between the rack and the actuating-lever; and a cam for moving the actuating-lever, all substantially as described, whereby the throw of the pawl-carrier may be varied to determine the number of chambers or pockets of the measuring-wheel brought to the delivery-point at each stroke.

700,867. WAGON-JACK. EDGAR A. PETER, Detroit, La. Filed Oct. 21, 1898. Serial No. 734,341. (No model.)

Claim.—A lifting-jack comprising in combination a base 5, carrying a standard 6, provided with side flanges 7 and 8, the lifting-jack 9 slidably secured between the said flanges, the edge of said bar being beveled to correspond with the inner walls of said flanges, the sliding head 10 adjustably held on the said bar 5, the pin 11 for securing the head, said pin engaging the perforation 12, the pin 14 secured upon the bar 5 and projecting through the slot 13, said pin 14 engaging the flange-bar 15 at one end and the curved lever 16 secured at 15, and the beam-bar 18 connecting the standard and base, and all arranged and adapted to operate substantially as shown and described.

700,868. DRILLING OR LIKE MACHINE. FRANK E. PIERCE, Herley, England, assignor to Lamson Moseley Machine Company, Washington, D. C., a Corporation of Virginia. Filed June 5, 1891. Serial No. 63,395. (No model.)

Claim.—1. In a drilling or similar machine the combination of the following elements, to wit: a revolving work-holding spindle; a feed-rod;

a reciprocating revolvable turret provided with blank and tool holders; an ejector for the feed-rod; an ejector for the turret tool-holder; and means controlled by the movements of the turret for alternately actuating said ejectors, the one for passing the blank from the feed-rod to the turret during one reciprocation of the latter, and the other for passing the blank from turret to spindle during a subsequent reciprocation of the turret; substantially as described.

2. In a drilling or similar machine the combination with a revolving work-carrying spindle provided with an ejector, and a feed-rod also provided with an ejector, of a longitudinally-reciprocating intermittently-revolvable turret provided with one or more tool-holders and a plurality of blank-holders, and actuating device for said ejectors for simultaneously effecting the transfer of blanks from the roadway and the spindle to the turret during one reciprocation of the latter; substantially as described.

3. In a drilling or similar machine the combination with a revolving work-carrying spindle provided with an ejector, and a blank-holding roadway also provided with an ejector, of a reciprocating and intermittently-revolvable turret provided with one or more tool-holders and a plurality of blank-holders, each of the latter furnished with an ejector, and actuating device for said ejectors deriving motion from the turret, for simultaneously transferring blanks from the roadway and the spindle to the turret during one reciprocation of the latter, and for simultaneously discharging one of said blanks and transferring the other to the spindle during the succeeding reciprocation of the turret; substantially as described.

4. In a drilling or similar machine the combination with a work-holding spindle connected to its driving-wheel through a clutch, of a revolvable and reciprocating turret acting both as a tool-holder and a blank-transferer, and means intermediate said turret and clutch for controlling the application of the latter, to stop the spindle during the transfer of the blank and start it in action for the application of the tool; substantially as described.

5. In a drilling or similar machine the combination with a revolving work-carrying spindle provided with an ejector, a blank holding and feed roadway and an ejector therefor, and a blank-receiving roadway, of a reciprocating and intermittently-revolvable tool-carrying turret provided with a plurality of blank-holders, an ejector for each of said blank-holders, and actuating device intermediate the turret and said ejectors, for effecting the transfer of blanks from the feed-ro roadway and the spindle to the turret and from the latter to the spindle and receiving roadway; substantially as described.

6. In a drilling or similar machine the combination with a revolving work-carrying spindle, of a reciprocating and intermittently-revolvable turret provided with a plurality of work-holders, a registering device controlling the position of the turret during its reciprocatory movement, ejectors carried by the work-holders, and an actuating means for said ejectors also carried by the turret and adapted to be engaged by the registering device at one stage of the rotary movement of the turret; substantially as described.

7. In a drilling or similar machine the combination with a revolvable work-holding spindle and its ejector, a feed-rod provided with an ejector, and a reciprocating and intermittently-revolvable tool-carrying turret provided with blank-holders, of a clutch engaged by the turret and opening through lever on the spindle-ejector and the feed-rod ejector to simultaneously discharge blanks into the turret work-holders, substantially as described.

8. In a drilling or similar machine, the combination with a revolvable work-holding spindle, a driving-pulley therefor, and a reciprocating and intermittently-revolvable turret, of a spring-actuated friction-clutch intermediate the driving-pulley and work-holding spindle, and a latch controlled by the turret in its movements and acting upon the clutch mechanism to disengage the spindle and arrest the latter in position to receive or deliver a blank; substantially as described.

9. In a drilling or similar machine the combination with a revolvable spindle and a reciprocating and intermittently-revolving turret, of a driving-pulley mounted between clutch-sections of the spindle, a spring for closing said clutch-sections, a detent for engaging one of said clutch-sections to open the clutch and arrest the spindle, a blank-retainer carried by the spindle and means for actuating said detent and retracting said blank-retainer, substantially as and for the purposes set forth.

10. In a drilling or similar machine the combination with a revolvable work-holding spindle, a driving-pulley therefor, a clutch intermediate said pulley and spindle, a blank-holder, and a reciprocating and intermittently-revolving turret, of an ejector for said spindle, means for actuating the spindle, retracting the blank-holder, and actuating the ejector, substantially as described.

11. In a drilling or similar machine the combination with a reciprocating and revolvable turret provided with a series of catches or ratchet-teeth, of an actuating-lever connected to the axle of the turret, and pivotally located in a plane transverse to the axis of the turret, and pivotally connected to the latter, said lever bearing a pawl or pin for engaging the catches on the turret, substantially as described.

12. In a drilling or similar machine the combination with a revolvable work-holding spindle, a feed-ro roadway, a receiving-ro roadway provided with a pusher, and ejectors for said spindle and feed-ro roadway, of a longitudinal reciprocating intermittently-revolvable turret provided with tool-holders and a plurality of blank-holders, the latter furnished with ejectors, a driving-pulley and clutch for the spindle, and actuating device controlled from and responding to the movements of the turret, for arresting and releasing the spindle, moving the ejectors and reciprocating the pusher; substantially as and for the purposes set forth.

13. In a drilling or similar machine the combination with a revolving work-holding spindle and reciprocating and intermittently-revolvable turret provided with one or more tool-holders and a transfer-blank holder, of a feed-ro roadway and a revolvable stick or galley provided with a blank-holding detent and adapted to cooperate with said roadway in the delivery of the blanks contained therein; substantially as described.

14. In a drilling or similar machine the combination with a revolving work-holding spindle and a reciprocating and intermittently-revolvable turret provided with one or more tool-holders, a blank-holder, and an ejector for the latter, of a receiving-ro roadway and a stick or galley detachably connected with said roadway and communicating with the receiving-chamber thereof; substantially as described.

15. In a drilling or similar machine, the combination with a feed race or compartment, a delivery race or compartment, and a revolvable spindle, having a blank-holding compartment in one end, of a turret having two blank-holding compartments, and a tool said turret being capable both of revolving on and of reciprocating in the direction of its axis, to transfer a blank from the feed-compartment to the spindle-compartment and from the spindle-compartment to the delivery-compartment and to place its tool in and withdraw it from operative position during each complete revolution, substantially as described.

16. In a drilling or similar machine, the combination with a turret capable both of revolving and of reciprocating motions of a casing and a pin, adapted to engage in slots in a flange on the turret to limit the reciprocation of the latter to predetermined points in its revolution, substantially as described.

17. In a drilling or similar machine, the combination with a turret capable of revolving upon and reciprocating in the direction of its axis, of an actuating-lever operating in two planes at right angles to each other for communicating said motion to the turret, substantially as described.

18. In a drilling or similar machine, and in combination, a casing E, a cylindrical turret having catches E', a handle F F', having one end working in a fixed guideway A', and with a pin F' adapted to engage the catches, the handle being pivotally connected with the turret so as to both reciprocate it endwise and revolve it in one direction within the casing, substantially as described.

19. In a drilling or similar machine a revolvable and reciprocating turret carried in a casing and having two blank-holding compartments in its face in combination with an ejecting-rod for each compartment connected by a bar E', and a lever operated by a pin E' to push each rod into its corresponding compartment during a forward movement of the turret, substantially as described.

20. In a drilling or similar machine the combination with a revolvable spindle and a revolvable and reciprocating turret, of a clutch-body secured to the spindle and having a conical friction-surface, a sleeve secured upon said clutch-body and provided with a conical friction-surface, a pulley located between said friction-surfaces, a pin carried by the clutch-body and projecting through a slot in the sleeve, a spring acting on said sleeve to rotate it in a direction to cause the engagement of the conical friction-surfaces with the pulley, an offset on the sleeve, a catch for said offset, and actuating device connected with the turret for causing said catch to engage the offset when the turret is in one position of adjustment; substantially as described.

21. In a drilling or similar machine the combination with a revolvable spindle having a blank-compartment opening in one end and a clutch mechanism and controlling device therefor, of a cap having an opening similar to the opening in the spindle end, a spring the tension of which normally holds the cap so that its opening does not coincide with the spindle-opening, an offset on the cap, and a catch to engage with the offset and cause the two openings to coincide synchronously with the arrest of the spindle, substantially as described.

22. In a drilling or similar machine and in combination, a revolvable spindle having a blank-compartment in one end and a spring-controlled clutch, a turret having two blank-holding compartments and one or more cutting-tools and capable of revolving upon and also of reciprocating in the direction of its axis when either a compartment or a tool coincides with the spindle-compartment, a flange on the turret the periphery of which forms a cam-surface, a rocking shaft, two arms on the rocking shaft one engaging the cam-surface the other carrying a catch adapted to engage an offset on the spindle-clutch, substantially as described.

23. In a drilling or similar machine and in combination, a feed-compartment and ejecting-rod G', a hollow revolvable spindle having a blank-

compartment in one end and an ejecting-rod within the spindle, a shaft H capable of reciprocation and a lever of which one end engages with a collar on the shaft A, while the other engages the delivery-compartment ejecting-rod, a second lever similarly engaged with the shaft H and the spindle ejecting-rod, and a flange on a reciprocating turret which engages one end of the shaft H during the forward movement of the turret causing the levers to drive the ejecting-rods into their respective compartments, substantially as described.

34. In a drilling or similar machine, the combination with a delivery-compartment having a spring-controlled ejecting-blade, of a reciprocating turret having a beveled pin on its front face adapted to drive the blade into the delivery-compartment longitudinally thereof during a forward movement of the turret, substantially as described.

700,869. UNIVERSAL JOINT. ALBERT A. FEXLEY, Birmingham, Mass. Filed July 20, 1901. Serial No. 70,011. (No model.)

Claim.—1. In combination with a shaft having a chamber in one end, a split socket 12 provided with a shaft and having slots in its sides, a second shaft having a ball at one end adapted to fit said socket, external pins on said ball to register with said slots, and means to secure said shaft in said chamber, substantially as shown and described.

2. In combination with a shaft having a chamber in one end, a split socket 12 provided with a shaft and having slots in its sides, a second shaft having a ball separated therefrom by a neck 11, said ball being adapted to fit said socket, external pins on the ball to register with said slots, and means to secure said shaft in said chamber, substantially as shown and described.

3. In combination, in a universal joint, a shaft chambered at one end, a second shaft having a pin-provided ball 11 at one end, and a dotted socket 12 comprising two halves provided with shaft-sections adapted to enter the recess in the first shaft, and means to secure said shaft-sections in said recess, said socket arranged to receive said ball with its pins in the shaft-slots, being being attached to said first shaft, substantially as shown and described.

700,870. PILL-MACHINE. WILLIAM RABER, St. Louis, Mo. Filed Sept. 18, 1901. Serial No. 70,002. (No model.)

Claim.—1. A compressor-die for pill-machine, comprising a casing, a die-plunger adjustably mounted in the casing, a spreading plunger and means for operating the same, substantially as specified.

2. A compressor-die for pill-machine, comprising a casing, a die-plunger adjustably mounted in the casing, an upwardly-moving plunger operating through the casing, and a spreading plunger for compressing the material, substantially as specified.

3. A compressor-die for pill-machine having a casing provided with a receiving-chamber, a die-plunger adjustably mounted in the chamber, a plunger operating through the casing for releasing the pill from the chamber, a plunger for compressing and forming the pill in the chamber, and means for spreading the same when released from the chamber, substantially as specified.

4. In a device of the class described, comprising a vertically-reciprocating plunger adapted to spread when released from the pressure-chamber, a casing for receiving the plunger for compressing the material to form the pill, and means for releasing the pill from the chamber at the upward movement of the plunger, substantially as specified.

700,871. PILL-MACHINE. GRANT H. RABER, St. Louis, Mo. Filed Sept. 9, 1901. Serial No. 70,003. (No model.)

Claim.—1. In a pill-machine, the combination of a frame, a hat-support, means for rotating the support, an inner horizontal lever supported by and having a vertical pivot on the frame, whereby it is enabled to swing in a horizontal plane, an outer horizontal lever connected by a vertical pivot to the inner lever so as to swing horizontally thereon, a device carried by the outer of said levers for operating on work on the support, and means for swinging the levers on the vertical pivot on the frame.

2. In a pill-machine, the combination of a frame, a hat-support, means for rotating the support, an inner horizontal lever supported by and having a vertical pivot on the frame, whereby it is enabled to swing in a horizontal plane, an outer horizontal lever connected by a vertical pivot to the inner lever so as to swing horizontally thereon, a device carried by the outer of said levers for operating on work on the support, and means for swinging the levers on the vertical pivot on the frame.

3. In a pill-machine, the combination of a frame, a hat-support, means for rotating the support, an inner horizontal lever supported by and having a vertical pivot on the frame, whereby it is enabled to swing in a horizontal plane, an outer horizontal lever connected by a vertical pivot to the inner lever so as to swing horizontally thereon, a device carried by the outer of said levers for operating on work on the support, and means for swinging the levers on the vertical pivot on the frame.

4. In a pill-machine, the combination of a frame, a hat-support, means for rotating the support, an inner horizontal lever supported by and having a vertical pivot on the frame, whereby it is enabled to swing in a horizontal plane, an outer horizontal lever connected by a vertical pivot to the inner lever so as to swing horizontally thereon, a device carried by the outer of said levers for operating on work on the support, and means for swinging the levers on the vertical pivot on the frame.

5. In a pill-machine, the combination of a frame, a hat-support, means for rotating the support, an inner horizontal lever supported by and having a vertical pivot on the frame, whereby it is enabled to swing in a horizontal plane, an outer horizontal lever connected by a vertical pivot to the inner lever so as to swing horizontally thereon, a device carried by the outer of said levers for operating on work on the support, and means for swinging the levers on the vertical pivot on the frame.

6. In a pill-machine, the combination of a frame, a hat-support, means for rotating the support, an inner horizontal lever supported by and having a vertical pivot on the frame, whereby it is enabled to swing in a horizontal plane, an outer horizontal lever connected by a vertical pivot to the inner lever so as to swing horizontally thereon, a device carried by the outer of said levers for operating on work on the support, and means for swinging the levers on the vertical pivot on the frame.

7. In a pill-machine, the combination of a frame, a hat-support, means for rotating the support, an inner horizontal lever supported by and having a vertical pivot on the frame, whereby it is enabled to swing in a horizontal plane, an outer horizontal lever connected by a vertical pivot to the inner lever so as to swing horizontally thereon, a device carried by the outer of said levers for operating on work on the support, and means for swinging the levers on the vertical pivot on the frame.

frame, and the links disposed at opposite sides of and extending in the same direction as the spindle, and connecting the ends of the lever and opposite sides of the yoke.

7. In a hat-machine, the combination of a frame, a primary shaft having a hat-support thereon, and also having a worm, a worm-wheel adapted to receive motion from said worm, and having a radial slot, and a wrist-pin adjustably secured therein, a reciprocating bar, a link interposed between and pivotally connected to the bar and the wrist-pin, and adjustable toward and from the center of the worm-wheel, a device for operating on work on the support, and means carrying said device and adapted to receive motion from the reciprocating bar.

700,872. GARMENT-HOOK. THOMAS DE QUARTER, Philadelphia, Pa. Filed Nov. 4, 1901. Serial No. 51,000. (No model.)

Claim.—1. A garment hook embodying a shank and a bill, and a plurality of bands existing at different points longitudinally of the structure and extending from said shank to said bill, the innermost band serving to engage an eye and being in the normal operation of the hook impossible to aid eye, and an inner and an outer band adapted to confine in position a shank securing thread passed between them.

2. A garment hook having a shank and a bill existing in approximately parallel planes, and having an eye passage between them, a strain receiving band extending across the distal end of said eye passage, and impossible to an eye entering said passage, and a member extending approximately perpendicularly to the planes of the shank and bill, and arranged at a point longitudinally of the hook a sufficient distance to the front of said band to afford space between itself and said band for a shank securing thread, substantially as set forth.

3. A garment hook having a shank and a bill, existing in approximately parallel planes, and having an eye passage between them, a strain receiving band extending across the distal end of said eye passage and impossible to an eye entering said passage, and a member extending approximately perpendicularly to the planes of the shank and bill, and arranged at a point a sufficient distance, longitudinally of the hook, to the front of said band to afford space between itself and said band for a shank securing thread, the respective ends of said last named member carrying into the hook structure.

4. A wire garment hook having a shank and a bill, arranged to form an eye passage between them, a band connective or continuous of said shank and bill, and a tongue wire member extending along the shank and having a head or portion extending from the shank to the bill and so disposed as to be out of line, viewed from the side of the hook, with the band first referred to, the innermost of said bands extending across the distal end of said eye passage and being impossible to an eye entering said passage, and the space between said bands containing a shank securing thread, substantially as set forth.

5. A wire garment hook comprising a shank formed of two wire lengths, a bill formed of two wire lengths, said shank and bill existing in approximately parallel planes, bands connective of the wire lengths of the shank and those of the bill, an additional member existing in part in proximity to the members of the shank and in part in proximity to the members of the bill, and embodying a strain receiving band extending across an eye passage between the shank and bill which band exists at a point clear to the rear end of the structure than are the bands first referred to, and is impossible in the normal operation of the parts to an eye entering said passage, substantially as set forth.

6. A wire garment hook comprising a shank formed of two wire lengths, a bill formed of two wire lengths, said shank and bill existing in approximately parallel planes, bands connective of the wire lengths of the shank and those of the bill, an additional member existing in part between the members of the shank and in part between the members of the bill and comprising a strain receiving band existing at a point clear to the rear end of the structure than are the bands first referred to, the ends of wire forming said additional member embodying also a locking projection, substantially as set forth.

7. A garment hook comprising two shank members, two bill members, two bands connective of said shank and bill members respectively, a member extending along the shank to a point near the outer portion of the latter and thence across the eye passage formed between the shank and bill, to a point between the two bill members referred to, the head of the member last referred to being clear to the rear end of the hook than are the bands first referred to, and constituting a strain receiving band to engage the complementary member of the fastening, and also serving to prevent the sliding rearwardly of a shank securing thread engaged with the outer and portions of the shank members.

8. A garment hook having a shank and a bill arranged to approximately parallel planes, between which shank and bill exists an eye pas-

sage, a strain receiving member extending from the shank to the bill at the distal end of said passage, which member is in the normal operation of the hook impossible to an eye entering said passage, and a shank securing thread opening or cut arranged at the front end of the hook beyond the eye passage, the member or members forming or defining which opening or cut are arranged in a plane approximately perpendicular with respect to the planes of the shank and bill.

700,873. DISTILLING APPARATUS. JOHN S. BAKER, Brooklyn, N. Y., assignor to W. H. K. Hale, Gustaf, N. Y., and Curtis W. Kirschtner, Englewood, N. J. Filed June 4, 1901. Serial No. 60,000. (No model.)

Claim.—1. In an apparatus of the character described, a condenser-coil, a pipe leading from a retort, an elbow connecting said pipe and the coil, a bend on said elbow, a tapered casing detachably mounted on said bend, a jet-nozzle extending into said casing and connected with a source of steam-supply, a pipe connecting said casing with an elevated tank, and a pipe also connected to said casing and with an open funnel, all substantially as and for the purposes specified.

700,874. DISTILLING APPARATUS. JOHN S. BAKER, Brooklyn, N. Y., assignor to W. H. K. Hale, Gustaf, N. Y., and Curtis W. Kirschtner, Englewood, N. J. Filed June 21, 1901. Serial No. 60,000. (No model.)

Claim.—1. In a distilling apparatus, a vapor-pipe leading from the retort to the worm, combined with a chamber of greater cross-sectional area than said pipe interposed in the same between the retort and worm, and a series of open-work trays in said chamber said trays having alternately-arranged flaps, as and for the purposes specified.

2. In a distilling apparatus, a retort, a vapor-pipe therefrom, a chamber of greater cross-sectional area than said pipe and to which said pipe leads, a downward extension of said pipe within said chamber, a vapor-pipe of less cross-sectional area than said chamber leading from the upper portion of the latter to the worm, and a plurality of receptacles within the chamber above the lower end of the extension and having alternately-arranged flaps, all combined and arranged to serve substantially as described.

3. In a distilling apparatus, a retort, a vapor-pipe therefrom, a chamber of greater cross-sectional area than said pipe and to which said pipe leads, a downward extension of said pipe within said chamber, one or more open-work trays located in said chamber with their counter troughs alternately arranged and adapted to support and prevent a combining agent to the vapor in said chamber, and a vapor-pipe of less cross-sectional area than said chamber leading from the upper portion of the latter to the worm, all combined and arranged to serve substantially as herein specified.

4. The retort A, vapor-pipe A' and chamber B, the extension H within said chamber, the open-work trays H' H' located in the latter one above the other, each comprising a series of counter troughs H'' having the member H''', the flaps to the uppermost tray coinciding with the chamber space between adjacent troughs on the lowermost, the vapor-pipe A' leading from the upper portion of said chamber to a worm, the binged bottom B' for said chamber, and a pipe D leading therefrom, all combined substantially as and for the purposes herein specified.

5. A retort, a chamber, a vapor-pipe connecting the two and having an extension within said chamber, open-work trays located in said chamber one above the other, each comprising a series of counter troughs hav-

ing smaller line, the line on the one corresponding with the smaller space between adjacent trays on the next adjacent, a vapor-pipe leading from the upper portion of the chamber to a worm, and an outlet from the bottom of said chamber, all substantially as described.

700,875. ELEVATOR-DOOR-OPERATING MECHANISM. HAROLD BOWYER, Chicago, Ill., assignor to the Harbott-Bowyer Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Nov. 20, 1901. Serial No. 35,305. (No model.)

Claim.—1. In an elevator-door-operating mechanism, the combination with a door, power mechanism for operating the same including a rotatable shaft, a rotating part driven therefrom, and eccentric connections between said rotating part and door, whereby the door when operated is moved at constantly-varying speed, as and for the purpose set forth.

2. The combination with a door, of operating mechanism therefor including a rotatable shaft, a rotating part driven therefrom, eccentric connections between said door and rotating part, and means for controlling the operation of said rotating part, as and for the purpose set forth.

3. The combination with a door, of an operating mechanism therefor including a rotatable shaft, a rotating part driven therefrom, an arm or lever connected to the door, and a link eccentrically connected to said rotating part and having connection with said arm or lever, as and for the purpose set forth.

4. The combination with a door, of an arm or lever connected thereto, a rotatable shaft, a rotating part adapted to be driven therefrom, a link connected to said arm or lever and eccentrically connected to said rotating part, and means controllable from the car for operating said rotating part, as and for the purpose set forth.

5. The combination with a door, a gear, a rotatable shaft, driving connections intermediate said shaft and gear for imparting relative movement to said gear, a link pivotally connected eccentrically to said gear, and connections between said link and door, as and for the purpose set forth.

6. The combination with a door and a rotatable shaft, of a rotatable gear adapted to be driven from said shaft, a link pivotally connected eccentrically to said gear, an arm connected to the door and to which said link is also connected, the point of connection of said link to said gear and arm being in substantial alignment with each other and with the axis of rotation of said gear when the door is in closed or opened position whereby the door is locked, as and for the purpose set forth.

7. The combination with a door, power mechanism for operating the same and including a rotatable shaft, a rotating part driven therefrom, connections between said rotating part and door for moving the same into closed or opened position, said connections operating in starting the door from a position of rest to move the door with a steadily-increasing speed, and at a steadily-decreasing speed as the car approaches its limit of movement, and means for controlling the operation of said power mechanism, as and for the purpose set forth.

8. The combination with a door, power mechanism for operating the same including a driving-shaft, pinions mounted on said shaft, a gear co-operating with said pinions, a link pivotally connected eccentrically to said gear, and connections between said link and door, as and for the purpose set forth.

9. The combination with a door, power mechanism for operating said door, including a gear, driving-pinions for said gear, connections between said gear and door, said gear provided with a blank space in the gear-face thereof, whereby it is brought to rest, as and for the purpose set forth.

10. The combination with a door, of a continuously-revolving shaft, pinions mounted upon said shaft, a gear, means for operatively connecting said gear and shaft through said pinions, a portion of the teeth of said gear being omitted, and connections between said gear and door, as and for the purpose set forth.

11. The combination with a door, of an operating mechanism therefor, including a gear having a portion of the teeth omitted therefrom, a

continuously-revolving shaft, pinions mounted thereon, means whereby said pinions complete operative connection between said gear and shaft, a link pivotally connected to said gear, and connections between said link and door, as and for the purpose set forth.

12. The combination with a door, of operating mechanism therefor, including a rotatable gear, a rotating shaft, pinions actuated thereby and forming operative connections between said shaft and gear, means for governing the operative connections between said pinions and gear, whereby either one or the other of said pinions are made operative with respect to said gear, and stops for arresting the movement of said gear, as and for the purpose set forth.

13. The combination with a door, of an operating-gear therefor, said gear provided with legs, pinions for actuating said gear, and means arranged to be engaged by said legs for arresting said gear at proper positions with reference to said pinions, as and for the purpose set forth.

14. The combination with a door, an operating-gear therefor having a portion of the teeth thereof omitted, pinions for actuating said gear, whereby said gear is arrested when the blank portion thereof arrives opposite an actuating-pinion, and means for maintaining said gear in position to hold said blank portion out of engagement with the operating-pinion, as and for the purpose set forth.

15. In an apparatus of the class described, the combination with a door-operating mechanism therefor, including a rotatable gear having a portion of the gear-teeth thereof omitted to form a blank space, driving-pinions for said gear, said gear provided with notches or seats in the periphery thereof, and means arranged to enter said notch or seat to maintain said gear in position to hold said pinions out of engaging relation with respect to said gear, as and for the purpose set forth.

16. The combination with a door, of operating mechanism therefor, including a shaft, a sleeve mounted upon said shaft for rotation therewith, but capable of longitudinal movement thereon, means controllable from the car for shifting said sleeve upon said shaft, a gear, pinions, the shifting of said sleeve affecting the operative connection of one or the other of said pinions with said gear, a link pivotally connected eccentrically to said gear, and connections between said link and door, as and for the purpose set forth.

17. The combination with a door, of mechanism for operating the same, including a gear, a rotatable shaft, a sleeve mounted upon said shaft for rotation therewith, but capable of longitudinal movement thereon and carrying pinions arranged when said sleeve is shifted to be brought respectively into engaging relation with respect to said gear, means for controlling the shifting movements of said sleeve from the car, a link pivotally connected at one end eccentrically to said gear, and means connected to the other end for operating the door, as and for the purpose set forth.

700,876. WHEEL-STOP. EDGAR A. RYAN, Rochester Springs, Mo. Filed July 6, 1901. Serial No. 67,299. (No model.)

Claim.—The combination of an axle, a wheel-hub encircling it, bearing device for mounting the lower end of the hub to turn on the axle, a plug fastened on the outer extremity of the axle and tapered toward its

outer end, a cap secured in the outer end of the wheel-hub to close it and including the plug, and bearing-balls held in the cap and running between it and the tapered surface of the plug.

700,877. GUMMED ROAD AND ICE SKATE. JULIUS SAUER, HANNOVER, GERMANY. Filed Dec. 2, 1900. Serial No. 32,108. (No model.)

Claim.—1. In an improved combined road and ice skate in combination with the base and customary means for attachment of the skate to the foot; two pairs of vertical bars attached to the base; a metal hoop interconnecting and clamping the aforesaid bars in their relative position; a pair of detachable axles supported in transverse bores in the vertical bars, means for securing said axles against rotation in their bearings and a pair of balls adapted to be received between the vertical bars and rotatable on the aforesaid axles, substantially as described and shown.

2. In an improved combined road and ice skate in combination with the base and customary means for attachment of the skate to the foot; two pairs of vertical bars attached to the base; a metal hoop interconnecting and clamping the aforesaid bars in their relative position; a pair of detachable axles supported in transverse bores in the vertical bars, means for securing said axles against rotation in their bearings and a skating-blade adapted to be received centrally between the vertical bars and to be secured in position by means of the aforesaid axles, substantially as described and shown.

3. In an improved combined road and ice skate in combination with the base and customary means for attachment of the skate to the foot; two pairs of vertical bars attached to the base; a metal hoop interconnecting and clamping the aforesaid bars in their relative position; a pair of detachable axles supported in transverse bores in the vertical bars; means for securing said axles against rotation in their bearings and a pair of balls and a skating-blade adapted to be interchanged, and to be received and supported between the vertical bars by means of the aforesaid axles, substantially as described and shown.

700,878. PIPE-COMPRESSOR. KARL SCHMIDT, Dresden, Germany. Filed Feb. 12, 1901. Serial No. 67,072. (No model.)

Claim.—1. In a pipe-compressor, the combination of stiff pipes and flexible pipe members as disposed to one another that the axis of the pipe whose longitudinal movement is to be compensated does not coincide with that of the one to be subjected to bending and means for limiting the bending of the flexible pipe.

2. The combination of stiff pipes with straight, or approximately straight, flexible pipe members and stiff form-pieces, connecting the said flexible pipe members.

3. In combination with a pipe-compressor, rods disposed transversely to the flexible pipes, with clamping shoulders for preventing excessive bending strains in the flexible pipes.

4. In combination with a compressor, a support with legs or the like, between which the connecting-flanges or special legs on the pipes are positioned, to prevent bending in a plane perpendicular to the direction of motion, and excessive tensile and compressive strains in the flexible pipes.

5. In combination with a compressor, a support with indentations for receiving the connecting flanges or legs on the pipes, for preventing bending of the flexible pipes in a plane perpendicular to the direction of motion and excessive tensile and compressive strains in the flexible pipes.

6. In combination with a compressor, a support with legs or the like, arranged in the direction of the axis of the piping, between which legs the connecting flanges or legs on the pipes come to rest, to prevent excessive bending of the flexible pipes.

7. In combination with a compressor, a support with indentations arranged in the direction of the axis of the piping, in which the flanges or legs on the pipes come to lie, to prevent excessive bending of the flexible pipes.

8. In combination with a compressor, a support with legs or the like, arranged in the direction both of the axis of the flexible pipe, and of the axis of the expanding piping, between which the connecting flanges or legs on the pipes are held, to prevent sagging, and excessive tensile and compressive strains and excessive bending of the flexible pipe.

9. In combination with a compressor, a support with indentations arranged in the direction of both the axis of the pipe to suffer bending as well as the axis of the pipe expanding, into which the connecting flanges or legs on the pipes are put, to prevent sagging, and excessive tensile and compressive strains and excessive bending of the flexible pipe.

10. The combination with a flexible compressor, of a support provided with rollers to facilitate the movement of the piping and means to restrain an excessive movement of the piping.

11. In combination with a flexible compressor, a support provided with a clamping device for fixing one point of the piping, so that its motion may take place toward one side only and rollers to facilitate the said motion.

700,879. AMALGAMATING-MACHINE. GEORGE C. BERRY, Columbus, Ohio. Filed June 20, 1901. Serial No. 66,692. (No model.)

Claim.—1. In an amalgamating-machine, the combination with a casing having an inlet-opening and outlet extension, said casing being adapted to contain a body of mercury and a rotating amalgamating-body within said casing adapted to run through said mercury, of an elevating device contained in said outlet extension, said elevating device comprising outer and inner wheels and a traveling apron connecting said wheels and means whereby a shaking or vibratory movement is imparted to said elevator, and a movable amalgamating device interposed between said rotating body and elevating device, substantially as specified.

2. In an amalgamating-machine, the combination with a casing having an inlet-opening and outlet extension and adapted to contain a body of mercury, of a rotating amalgamating-body within said casing to run in said mercury, an elevating device located in said outlet extension, means for operating said elevating device, and an interposed traveling amalgamating-carrier having transverse mercury-cups, as and for the purpose specified.

700,880. TELEPHONE OR TELEGRAPH SYSTEM. EDGAR SMITH, West Lafayette, Ind. Filed Sept. 17, 1900. Serial No. 59,364. (No model.)

Claim.—1. In a telephone and telegraph system, a spring-jack including a pair of contact-strips normally in contact, and a pair of contact-strips normally isolated but capable of alternative connection with one strip of the first pair after it is separated from the other strip of the first pair.

2. In a telephone and telegraph system, a spring-jack including a pair of contact-strips normally in contact, a pair of contact-strips nor-

mally isolated, and a plug that separates the first pair of contact-strips and while entering connects one of the first pair with one of the second pair and when in place leaves the later separated but connects one only of the first pair with the other strip of the second pair.

3. In a telephone or telegraph system, a jack having two springs engaged by the plug when inserted, and two conducting-strips not engaged by the plug, one of said springs being connected with one of the strips while the jack is not in use and disconnected while in use, and momentarily connected with the other strip while the plug is being inserted in the jack.

4. In a telephone or telegraph system, a jack having two springs engaged by the plug when inserted and two conducting-strips not engaged by the plug, one of said springs being connected with one of said strips when the jack is not in use, and adapted to be held away from said strip by the plug when inserted and momentarily connected with the other strip as the plug is being inserted, and insulating means whereby said strip is disconnected by the other spring when it is engaged by the plug.

5. In a telephone and telegraph system, the two wires of a circuit, one of which wire is broken or separated, a spring-jack having a pair of contact-strips normally in contact with each other and connected with the respective ends of the broken wire and a pair of contact-strips normally isolated but capable of alternate connection with one strip of the first pair after it is separated from the other strip of the first pair, and a connection between said second pair of strips and the unbroken wire of the circuit.

6. A telephone or telegraph system including the two wires of a circuit, one of which wire is broken, a jack, having two springs adapted to be engaged by the plug, when inserted and two conducting-strips not engaged by the plug, one of said springs being connected with one of the strips while the jack is not in use and disconnected while in use and momentarily connected with the other strip while the plug is being inserted in the jack, wires leading from said connecting spring and strip to the members of the broken circuit-wire, a battery, wires leading from the other spring and strip to the battery, and a wire from the battery to the unbroken circuit-wire.

700,881. THEATRICAL APPLIANCE. JOHN W. GERRARD, New York, N. Y., assignor to himself and John Louis Sherman, New York, N. Y. Filed Dec. 26, 1900. Serial No. 41,500. (No model.)

Claim.—1. In a theatrical appliance of the class described, a transparent reflecting-screen arranged upon the stage at an angle with the plane of the front of the stage, said transparent reflecting-screen being provided with a framework backing, a compartment arranged at one side of said screen, lighting means for said compartment, lighting means arranged rearwardly of said screen, and controlling means whereby the lighting means for said compartment and the lighting means rearwardly of said screen may be varied in relative power.

2. In a theatrical appliance of the class described, a transparent screen arranged vertically upon the stage at an angle with the plane of the front of the stage, said screen being provided with a framework backing, lighting means arranged forwardly of said screen, lighting means arranged rearwardly of said screen, and controlling means whereby said lighting means forwardly of said screen and said lighting means rearwardly of said screen may be varied in relative power.

3. In a theatrical appliance of the class described, a transparent screen arranged vertically upon and obliquely transversely of the stage, a cabinet arranged at one side of the stage and adjacent the side edge of said transparent screen farthest from the front of the stage, a framework or frame screen arranged rearwardly of said transparent screen, lighting means for said cabinet, lighting means arranged rearwardly of said trans-

parent screen, lighting means arranged rearwardly of said framework or frame screen, and controlling means for each of said lighting means whereby the power of said several lighting means may be relatively varied.

4. In a theatrical appliance of the class described, a transparent screen arranged vertically upon and obliquely transversely of the stage, and a framework or frame screen arranged rearwardly of said transparent screen, lighting means arranged rearwardly of said transparent screen, lighting means arranged rearwardly of said framework or frame screen, and controlling means for each of said lighting means whereby the power of said several lighting means may be relatively varied.

5. In a theatrical appliance of the class described, a transparent reflecting-screen arranged vertically upon the stage at an angle with the plane of the front of the stage, said transparent reflecting-screen being provided with a framework backing, substantially described and for the purpose specified.

6. In a theatrical appliance of the class described, a transparent reflecting-screen arranged vertically upon and obliquely transversely of the stage, said transparent screen being provided with a framework backing, and a framework or frame screen arranged rearwardly of said transparent screen and transversely of the stage.

700,882. SOUND-REPRODUCING APPARATUS. EDWARD D. SHARP, Cincinnati, Ohio. Filed Sep. 16, 1901. Serial No. 58,115. (No model.)

Claim.—1. A horn composed of two dome-shaped plates of metal united at their lower edges, and having a series of tubes arranged in one or more horizontal rows near its lower edge as herein shown and described.

2. In combination with the dome-shaped horn provided with a series of tubes arranged in one or more horizontal rows near its lower edge, the dome-shaped horn composed of two sheets or plates of metal united so as to be water-tight and provided with suitable inlets and outlets, said horn being of such shape and size as to completely envelop the horn and have a space all around between it and the horn for the passage of the products of combustion, substantially as and for the purpose set forth.

700,883. FISH-BOAT. GEORGE S. SMITH and FRANK T. SMITH, Athens, Mich. Filed Aug. 29, 1901. Serial No. 73,704. (No model.)

Claim.—1. A composite frame-post consisting of a sheet-metal link with wire loops connected to one side bar thereof and projecting outwardly, and a cement covering for said link and wire except the outer head or light of the loops.

2. A composite frame-post consisting of a sheet-metal link having its side bars corrugated transversely, a connected series of wire loops attached to one of the side bars of the link and projecting outwardly, and a composition covering the link and all but the outer extension or light of the wire loops.

3. A composite frame-post having a sheet-metal channel formation composed of a tapered metallic link corrugated transversely, a series of connected wire loops rigidly secured to one bar of the link and projecting therefrom, and a composition covering for the link extending nearly to the outer turn of the loops, all substantially as described.

700,884. SEPARATOR. EDWARD C. SHARPE, Victor, Colo. Filed Sept. 28, 1901. Serial No. 73,590. (No model.)

Claim.—In a separator for drilling-machine actuated by compressed air, the combination with a casing having at its lower end a draw-off flange, an inlet compressed-air pipe secured to the top of the casing, an outlet air-pipe secured to the bottom thereof and extending into the casing, a head formed on the upper end of said outlet-pipe having elongated laterally opposite straight open ends, said pipes and said head being of such relative size that the compressed air forced through the inlet-pipe is deflected on the elongated ends of the head to fill the casing before the compressed air is permitted to find an exit through said open ends of said head and then into and out of said outlet-pipe, substantially as specified.

700,885. CHURN. EDWARD H. SWENHAM, Kansas City, Mo. Filed July 12, 1901. Serial No. 61,254. (No model.)

Claim.—1. In a churn, the combination of a bell-shaped whip open at its lower end, and provided with a relatively small opening in its upper face above the line of immersion; and a flexible shaft connected to the upper end of the whip and forming its sole means of support; and means for rotating said shaft.

2. In a churn, the combination of a bell-shaped whip, open at its lower end and having a series of downwardly-inclined openings formed in its upper end; and a flexible shaft connected to the upper end of the whip and forming its sole means of support; and means connected to said shaft for imparting rotary motion thereto.

3. In a churn, the combination of a bell-shaped whip, open at its lower end, and having a series of downwardly-inclined openings in its upper end; and a flexible shaft connected to the upper end of the whip and forming its sole means of support; a spindle connected to said shaft, said spindle being mounted in fixed bearings; a pulley carried by said spindle; and means for imparting motion thereto.

4. In a churn, the combination of a receptacle; a whip having imperforate side walls mounted therein; means for imparting rotary motion to said whip and causing it to move about in the receptacle in an irregular path; and means for permitting air to pass into the interior of the whip and out through the bottom of the same.

700,886. AUTOMATIC SWITCH. JAMES A. TARDON and THOMAS C. OGDEN, London, Canada. Filed Mar. 14, 1901. Serial No. 61,439. (No model.)

Claim.—1. In an automatic switch, the combination of a head-block, two independent plungers vertically movable therein, a pivoted foot carried by one of said plungers, a cam-wheel and connections between said cam-wheel and each of said plungers for reciprocating the same.

2. In an automatic switch, the combination of a head-block, two independently-movable plungers working therein, a pivoted foot carried by the innermost plunger, a cam-wheel, connections between the same and the plungers, for reciprocating the latter, and a spring acting on said foot to keep it normally in a predetermined position, as set forth.

3. In an automatic switch, the combination of a head-block, two independently-movable plungers therein, a pivoted foot on one of the plungers, a cam-wheel with grooves, a projection on the outer plunger movable in said grooves and an effect on the other plunger actuated by means on the shaft of said cam-wheel, as set forth.

4. In an automatic switch, the combination of a head-block supported from the car-truck, and having socket square at its upper end and oblong at its lower end, plungers in said head-block, one within the other, a spring in the head-block bearing against the outermost plunger, lateral projections on said plungers, and a cam-wheel and connections for engaging both of said projections to operate the plungers, as set forth.

5. In an automatic switch, the combination of a head-block having socket square at its upper end and oblong at its lower end, two independently-movable plungers within the head-block, one within the other, a spring in the head-block acting on the outermost plunger, lateral projections on the plungers at their upper ends, a cam-wheel and connections for engaging the said projections to operate the plungers, the outer plunger being square and the inner one round and working in a correspondingly-shaped socket in the outer plunger and springs on opposite sides of the pin that engages the projection of the inner plunger, all substantially as shown and described.

700,887. VALVE-CONTROLLING MECHANISM FOR AUTOMATIC WATER-METER. JAMES TRACY and WILLIAM A. BRADLEY, Allegheny, Pa., assignors by direct and mesne assignments, to the Buffalo Automatic Instantaneous Water Meter Co., Allegheny, Pa., a Corporation of Pennsylvania. Filed Apr. 12, 1901. Serial No. 61,611. (No model.)

Claim.—1. In a water-meter, the combination with a casing having gas inlet and outlet and water inlet and outlet, of a valve controlling communication between the gas inlet and outlet, a perforated hollow piston seated between the water inlet and outlet and controlling communication between the same through its ports, said valve and piston being connected to move in unison and said piston being exposed to and moved from its

out by, a preponderance of water-pressure on one of its sides to thereby open the gas-valve and also establish communication between the water inlet and outlet, a second piston, arranged on the outlet side of the first piston as to be actuated in one direction by back pressure, a lever connected with said second piston and with the first piston and valve, and an adjustable fulcrum for said lever.

2. In a water-heater, the combination with a casing having gas inlet and outlet and water inlet and outlet, and a valve controlling communication between the gas inlet and outlet, of a piston having a lateral part arranged between the water inlet and outlet and controlling communication between the same through its ports, said piston being connected with said valve and exposed to and operated in one direction by the water-pressure thereunder, a chamber arranged on the outlet side of said piston, a piston in said chamber exposed to and operated in one direction by the back pressure, and a connection between said pistons whereby they are caused to operate simultaneously and in reverse directions.

3. In a water-heater, the combination with a casing having a gas inlet and outlet and a water inlet and outlet, of a valve controlling communication between said gas inlet and outlet, a piston connected with said valve and controlling communication between the water inlet and outlet, said piston having a lateral part through which said communication takes place and embracing means by which the size of the part is adjusted to thereby determine the extent of movement of the piston and valve, and a returning means for the piston and valve.

4. In a water-heater, the combination with a casing having a gas inlet and outlet and a water inlet and outlet, a valve controlling communication between said gas inlet and outlet, and a stem carrying said valve, of a piston mounted on said stem and actuated by water-pressure to raise the same, said piston having lateral ports and embracing means for adjusting the size of its ports to thereby determine the extent of movement of said piston and valve and controlling communication between the water inlet and outlet through said ports, and a returning means for said piston and valve, said returning means acting in opposition to the main water-pressure to which said piston is exposed.

5. In a water-heater, the combination with a casing having a gas inlet and outlet and a water inlet and outlet, a valve controlling communication between said gas inlet and outlet, and a stem carrying said valve and projecting therefrom into the space between said water inlet and outlet, of a piston attached to said stem and operating in said space as to control communication between said water inlet and outlet, said piston being arranged to be exposed to main pressure and comprising two hollow cup-shaped members each provided with ports and attached to said stem and having a relative adjustment of its members on said stem by which the size of the ports may be changed and the extent of movement of the stem varied, means for fixing the piston in adjusted position on said stem, and means controlled by back pressure for lowering said stem and thereby returning said piston and valve to their respective seats.

6. In a water-heater, the combination with a casing having a gas inlet and outlet and water inlet and outlet, a valve controlling communication between said gas inlet and outlet, and a stem carrying said valve and projecting therefrom into the space between said water inlet and outlet, of a piston operating in said space as to control communication between said water inlet and outlet, said piston being arranged to be exposed to main pressure and comprising two hollow cup-shaped members each having lateral ports, one of said members being arranged within the other and both having their closed upper ends flared upon said stem, and means controlled by back pressure for lowering said stem and thereby returning said piston and valve to their respective seats.

7. In a water-heater, the combination with a casing having gas inlet and outlet and water inlet and outlet, and a valve controlling communication between the gas inlet and outlet, of a stem carrying said valve and projecting therefrom into the space between the water inlet and outlet, a piston attached to said stem and operating in said space as to control communication between said water inlet and outlet, said piston being arranged to be exposed to main pressure and comprising two hollow cup-shaped members each provided with ports and attached to said stem and having a relative adjustment of its members on said stem by which the size of the ports may be changed and the extent of movement of the stem

varied, means for fixing the piston in adjusted position on said stem, and means controlled by back pressure for lowering said stem and thereby returning said piston and valve to their respective seats, said returning means comprising a piston arranged on the water-outlet side of the ported piston as to be exposed to back pressure in advance of said ported piston, and a connection between said pistons whereby they are caused to operate simultaneously and in reverse directions, one from the other.

8. In a water-heater, the combination with a casing having tubular extensions adapted for connection with inlet and outlet water-pipes and provided with a piston-rod between said extensions, a gas-chamber fitted to said casing below the inlet to said casing and having an inlet and an outlet, a valve in said chamber for controlling communication between the inlet and outlet of said gas-chamber, a rod carrying said valve and projecting through said casing to a place above the same, a hollow ported piston attached to said stem and controlling communication between said tubular extensions through its ports, a chamber applied to the outlet extension, a piston in said chamber having a stem projecting through the same, a leg upon said extension having an elongated slot, a lever having its ends engaged with said rod and stem and provided with an elongated slot between its ends, a link upon which said lever is pivoted, and means cooperating with said slot in the leg and lever for actuating said link adjustably thereon.

700,888. TEMPORARY BINDER. ROBERT A. THOMAS, St. Louis, Mo., assignor to the Huber & Trussell Manufacturing Company, St. Louis, Mo., a Corporation. Filed July 21, 1900. Serial No. 24,272. (No model.)

Claim.—In a temporary binder, the combination of a pair of covers, hinge-arms pivotally united and coated in said covers, prongs carried by said arms, a plate secured to each of said arms, and strips providing connections between corresponding hinge-arms on the same side of the hinge; said covers being secured between said plates and strips, substantially as described.

700,889. ARTIFICIAL FUEL. ALEXANDER R. TUCKER, Birmingham, Ala., and OLIVER GUY, Birmingham, England. Filed Oct. 4, 1891. Serial No. 77,872. (No specimens.)

Claim.—1. Blocks or briquets of artificial fuel consisting in part of an agglutinant formed from the molten matter of sage-yielding plants, as set forth.

2. In blocks or briquets of artificial fuel, the combination with crushed or finely-divided fuel of an agglutinant composed of the non-fibrous part of the molten matter of sage-yielding plants, as set forth.

3. In blocks or briquets of artificial fuel, the combination with crushed or finely-divided fuel of an agglutinant composed of sage-flour, as set forth.

4. In blocks or briquets of artificial fuel, the combination consisting of crushed or finely-divided fuel, an agglutinant formed from the molten matter of sage-yielding plants, and oblongness matter, as set forth.

700,890. AUTOMATIC PIANO OR ORGAN PLAYER. BENJAMIN L. WATSON, Corinth, Mo. Filed Mar. 1, 1902. Serial No. 98,198. (No model.)

Claim.—1. In an automatic player, a transparent sliding cover provided with an opening in the top and a recess in the front wall, said cover

adapted to cover the working mechanism of the instrument and a removably-attachable apron adapted to fit on the rear wall of the player and rest upon the keys of the instrument to be played.

2. In an automatic player, a transparent cover, an opening in the top and a recess in the front wall near the bottom thereof, said cover adapted to cover the rolls and mechanism of the instrument and a removably-attachable apron consisting of a vertical wall, a horizontal ledge and a clamping device for holding the same on the back of the player.

3. In an automatic player, a suitable casing having a cover attached thereto, a supplemental transparent cover with a recess in the front wall near the bottom thereof and means for holding said supplemental cover in place, an apron removably attached to the rear wall of the player, said apron consisting of a vertical wall, a horizontal shelf angularly disposed to said wall and situated near the bottom thereof and spring-clamps for holding said vertical wall against the rear wall of the player.

4. In an automatic player, a suitable casing having an opening therein, a cover attached to said casing and adapted to cover said opening, a supplemental transparent cover removably attached to said casing and beneath said cover, said supplemental cover being provided with a recess in the front wall at or near the bottom, means for allowing said supplemental cover to be opened and to hold the same in place, a removably-attachable depending apron consisting of a vertical wall, a horizontal shelf angularly disposed thereto and situated near the bottom thereof and a clamping device on said vertical wall for holding it to the wall of a player.

5. In an automatic player, a suitable casing having an opening therein, a cover over said opening, a supplemental transparent cover removably attached to said casing and beneath said cover, said supplemental cover being provided with a recess in the front wall at or near the bottom, a removably-attachable depending apron consisting of a vertical wall, a horizontal shelf angularly disposed thereto and situated near the bottom thereof, clamping devices on said vertical wall adapted to hold said apron in position and allow the keys of an instrument to be played without interfering with the action thereof.

700,891. CARD-INDEX FILE. GEORGE F. WATTS, Chicago, Ill. Filed July 24, 1901. Serial No. 68,616. (No model.)

Claim.—1. A card-index file having an adjustable angle-block, cards provided with slots extending both vertically and horizontally; a pair of rods, whereof one is revolvably supported in the card-receptacle and forms a guide for the angle-block, and the other of said rods is connected to said guide-rod above the same for entering the slots within the cards, and means for throwing said retaining-rod laterally about the guide-rod as an act.

2. A card-index file comprising a casing, a drawer sliding therein, cards provided with slots extending both vertically and horizontally; a retaining-rod mounted in said drawer and capable of lateral motion for retaining or releasing the cards, said rod having a part projecting beyond the inner extremity of said drawer; and a locking-block secured to said casing, said block having an oblique face for engaging and laterally shifting said retaining-rod to retain said cards.

3. In a card-index file, the combination with the casing and drawer sliding therein, of an adjustable angle-block, cards provided with slots having both horizontal and vertical portions, a guide-rod for said angle-block journaled in the drawer, arms extending from said guide-rod, a retaining-rod carried by said arms and capable of lateral motion for engaging and releasing said cards, said retaining-rod projecting beyond the inner extremity of said drawer, and a locking-block having an oblique face adapted to engage said retaining-rod, whereby said rod is laterally shifted when said drawer is pushed home.

4. In a card-index file, the combination with the card-receptacle of an angle-block, a rod for guiding the same, a spring secured thereto, a sleeve hinged to said block and loosely enclosing said guide-rod, and said spring forcing said sleeve against said rod for cramping the latter to thereby prevent the travel of said angle-block, a lever mounted in said angle-block, said lever being connected to said sleeve for raising the same free from said rod, and means for operating said lever.

5. In a card-index file the combination with the card-receptacle of an angle-block, a rod for guiding the same, a spring secured to said block, a sleeve hinged to said block and loosely enclosing said guide-rod, said spring forcing said sleeve against said rod for cramping the latter to thereby prevent the travel of said angle-block, a lever mounted in said block,

and pivoted between its walls, a rod connecting said lever to said sleeve for raising the latter free from said rod and a button secured to said lever, said button and sleeve-operating rod being on opposite sides of the lever-pivot, whereby the pressing of said button releases said sleeve.

6. In a card-index file, the combination of a drawer for containing the cards, a spring for locking said drawer, cards provided with slots having portions extending horizontally and vertically, an adjustable angle-block, a guide-rod for said angle-block journaled in the side of the drawer, arms extending from said guide-rod, a retaining-rod carried by said arms and capable of lateral motion for engaging and releasing said cards, said retaining-rod projecting beyond the inner extremity of said drawer, a locking-block secured to said casing, and having an oblique face for shifting said guide-rod, a sleeve hinged to said angle-block and loosely enclosing said guide-rod, a spring secured to said angle-block and operating upon said sleeve to force the latter against said rod, a lever pivotedly mounted in said angle-block, a hand-operated button attached to said lever, and connections between said lever and said sleeve whereby the latter may be released from the guide-rod.

700,892. MATCH-MACHINE. KARL WINNBERG, Rudolfsburg, Germany. Filed Apr. 7, 1900. Serial No. 11,906. (No model.)

Claim.—1. In a match-machine of the class described the combination of a portable frame, spears carried thereby, a stationary frame having arms which carry guide-rollers for the threads coming from the spears, a wax-trough having guide-rollers in front and draw-clips at its end for the passage of the threads, a steam-bar, a cooling-bar having draw-clips at its end, a cooling-bar furnished with a fan, means to guide the threads, a pair of endless chains passing around pulleys at the ends of a frame and guided by angle-irons secured to the top and bottom parts of said frame, conveyor-bars having clamping-springs hinged to one end of them and catches fixed to the other end of the same, an arm pivoted to the frame and connected by a rod to a cam adapted to impart oscillating movement to said arm for engaging the end of the clamping-spring with said catches, substantially as specified.

2. In a match-machine of the class described the combination with a pair of endless chains to which intermittent motion is imparted, conveyor-bars having clamping-springs hinged to them for holding the match-threads thereon, and catches locking the springs upon the bars, of an upper shaft held by its ends in slotted guides and connected by rods to lever-arms bearing upon cams, and a lower shaft pivoted to levers connected by rods to said lever-arms for imparting opposite movement to said levers, substantially as specified.

3. In a match-machine of the class described the combination with a pair of endless chains passing around pulleys at the ends of a frame and guided by angle-irons at the top and bottom parts of said frame, conveyor-bars having clamping-springs hinged to one end of the bars and catches fixed to the other end of the same, of square heads arranged on one end of the bars and furnished with pins, guide-bars secured to the frame and forming a sliding surface for the heads, said guide-bars being provided with notches and pins, with which the square heads and pins engage in the forward movement of the conveyor-bars, substantially as specified.

4. In a match-machine of the class described the combination, with a pair of endless chains passing around pulleys at the ends of the frame and guided by angle-irons at the top and bottom parts of said frame, conveyor-bars having clamping-springs hinged to one end of the bars and catches fixed to the other end of the same, a trough containing ignition material, eccentric-rolls attached thereto and made in two parts connected by arms engaging with right and left handed screw-threads, and eccentrically adapted to impart reciprocating movement to said trough, substantially as specified.

5. In a match-machine of the class described the combination, with a pair of endless chains passing around pulleys at the ends of a frame and guided by angle-irons at the top and bottom parts of said frame, conveyor-bars having clamping-springs hinged to one end of the bars and catches fixed to the other end of the same, of hook-shaped levers pivoted

in brackets on the frame, crank-disks connected by rods to said levers, and by bevel-gear to the driving-shafts of the machine to release the clamping-springs from said catches, substantially as specified.

6. In a match-machine of the class described the combination, with a pair of endless chains passing around pulleys at the ends of a frame and guided at the top and bottom parts of said frame, conveyor-bars having clamping-springs hinged to one end of the bars and catches fixed to the other end of the same, a channel adapted to be moved upward and downward in guides on the frame, lever-arms bearing upon same on the driving-shafts and connected to the channel by rods, substantially as specified.

700,898. CANAL-BOAT. DANIEL H. WRIGHT, Buffalo, N.Y. Filed Dec. 13, 1891. Serial No. 85,797. (No model.)

Claim.—1. A boat comprising spaced keelsons and transverse floor-timbers, lining-plates disposed with their edges adjacent the keelsons and means removably connected with the keelsons and bearing against the plates for holding the latter against the floor-timbers.

2. In a boat, the combination with a keelson and floor-timbers connected thereto, of a lining disposed removably against the floor-timbers and with its edges adjacent the keelson, and means engaged with the keelson and bearing against the lining to hold the latter against the floor-timbers.

3. A boat comprising a keelson and floor-timbers lying at right angles thereto, a lining disposed against the floor-timbers with its edge adjacent the keelson, means removably engaged with the keelson and disposed against the lining to hold the latter against the floor-timbers, and packing disposed between the holding means and the lining.

4. A boat comprising a keelson having floor-timbers lying at an angle thereto, a lining disposed against the floor-timbers with its edge adjacent the keelson, a strip disposed in the angle between the lining and keelson and having its free edge adjacent the lining beveled in the direction of the keelson, packing disposed between the beveled face and the lining and the keelson, and means for holding said strip in said angle.

5. A boat comprising a keelson having floor-timbers lying at right angles thereto, a lining disposed against the floor-timbers with its edge adjacent the keelson, a strip disposed in the angle between the lining and keelson and having its free edge adjacent the lining beveled in the direction of the keelson, packing disposed between the beveled face and the lining and the keelson, means for holding the strip in said angle, and a metallic bulkhead disposed at each end of the boat.

700,894. VENDING-MACHINE. SAMUEL A. WILSON, Chicago, Ill., assignor, by direct and mesne assignments, to Standard Vending Company, Chicago, Ill., a Corporation of Illinois. Filed Aug. 20, 1891. Serial No. 73,299. (No model.)

Claim.—1. The combination in vending apparatus, of a holder for the article being vended having pockets with rigid divisions between them, a delivery-opening at which the cigars are delivered, means for causing the successive exposure of the pockets at the opening, and a package for the cigars having pockets corresponding to the pockets of the holder, and having the divisions between its pockets recessed so they will sit over the divisions on the holder, substantially as specified.

2. The combination in vending apparatus, of a holder for the article being vended having pockets with rigid divisions between them, a delivery-opening at which the cigars are delivered, means for causing the successive exposure of the pockets at the opening, and a package for the cigars having pockets corresponding to the pockets of the holder, and having the divisions between its pockets recessed so they will sit over the divisions on the holder, substantially as specified.

3. The combination in vending apparatus, of a package provided with pockets in which the articles to be sold are placed, and a holder or support for said package having pockets receiving the pockets of the package, substantially as specified.

4. The combination in vending apparatus, of a package provided with exterior pockets in which the articles to be sold are placed, and a circular holder or support for the package also having exterior pockets fitting the under surface of the package, substantially as specified.

5. The combination in vending apparatus, of a package containing the articles to be sold in pockets or divisions and a holder adapted to receive and support said package and provided with pockets or divisions corresponding to the pockets or divisions of the package, said holder being movable and acting to present the pockets of the package successively at the delivery-opening of the apparatus, substantially as specified.

700,895. CIGAR-PACKAGE. SAMUEL A. WILSON, Chicago, Ill., assignor, by direct and mesne assignments, to Standard Vending Company, Chicago, Ill., a Corporation of Illinois. Filed Dec. 20, 1891. Serial No. 85,800. (No model.)

Claim.—1. The package for articles to be vended in a vending-machine, consisting of a circular flat disk or plate and hollow divisions attached to the side of the disk and forming the pockets for the articles to be vended, the disk being adapted to permit the entry within said divisions of the division-plates upon the holder of the vending-machine, substantially as specified.

2. The package for articles to be vended in a vending-machine, consisting of a circular flat disk or plate and hollow divisions attached to the side of the disk and forming the pockets for the articles to be vended, that portion of the disk under the divisions being of a diameter which will permit the entry within the divisions of the division-plates of the holder of the vending-machine, substantially as specified.

3. The cigar-package consisting of a flat disk or plate provided with individual pockets for the cigars on its side, said disk being notched out under each division between the pockets, substantially as specified.

4. The cigar-package consisting of a flat circular disk or plate with individual pockets for the cigars on its side, and a ring 18 closing the inner ends of the pockets, substantially as specified.

5. The closed cigar-package consisting of the flat disk having cigar-pockets 11 on its side, the ring 18 closing the inner ends of the pockets, and the cover 19, 20, closing the side and outer ends of the pockets, substantially as specified.

6. The cigar-package consisting of a flat disk or plate provided with individual pockets for the cigars on its side, said disk being notched out under each division between the pockets, and the divisions being also recessed or hollow to permit the entrance within them of the divisions upon the holder of the vending-machine, substantially as specified.

7. The package herein described, consisting of a connected series of pockets made of flexible material and bent into endless form, a disk 10 to which the pockets are attached, a ring 18 closing the inner ends of the pockets, and an annular flanged cover clipped over the pockets and secured to the disk substantially as specified.

8. The package herein described, consisting of a connected series of pockets made of flexible material and bent into endless form, a disk 10 to the outer portion of which the pockets are attached leaving the center of the disk uncovered, means for closing the inner ends of the pockets, and a cover for the pockets having its center cut out so as not to conceal the center of the disk, substantially as specified.

9. The cigar-package herein shown consisting of an endless series of pockets arranged radially around a central opening, a plate forming a back to the pockets and also closing said opening, and a cover closing the front of the pockets without covering said central opening, substantially as specified.

700,896. DANFEL. ROBERT WYTHE, Hannover, Germany. Filed June 22, 1891. Serial No. 85,810. (No model.)

Claim.—1. The combination of a stove having an exit-flue and a draft-opening with a damper in said exit-flue having a hollow spindle extending through the walls thereof and communicating with the external air, said spindle being provided with an aperture within the exit-flue, and said flue being provided with a plate adapted to close said aperture when the damper is opened, a pivoted draft-door adapted to close said draft-opening and carrying a rack and a rod connected to said damper-spindle and provided with a gear-sector adapted to mesh with the rack on the draft-door.

2. In a damper for stoves, the combination of a stove having an exit-flue and a draft-opening with a damper in said exit-flue, having a hollow spindle extending through the walls thereof and communicating with the external air, said spindle being provided with an aperture within the exit-flue, and a plate in said exit-flue adapted to close said aperture when the damper is opened, a rod connected to said hollow spindle and pivoted in the stove-bottom, a gear-sector mounted on said rod and carrying an arm, and a pivoted draft-door, adapted to close the draft-opening and carrying a rack which meshes with the gear-sector when the rod is rotated to move the door laterally, the said door being raised when engaged by the arm carried by the gear-sector, substantially as described.

700,897. PERAMBULATOR. SAMUEL F. WITTEBOW, Cincinnati, Ohio. Filed Oct. 21, 1891. Serial No. 73,464. (No model.)

Claim.—1. A perambulator or carrier comprising a receptacle for retaining a child, wheels suitably mounted and connected with said receptacle, and mechanism connected with said receptacle whereby the same may be wheeled or carried while in operative condition, substantially as and for the purpose specified.

2. A perambulator or carrier comprising a receptacle provided with a seat, wheels suitably mounted and connected with said receptacle, and mechanism for throwing the perambulator into or out of wheeling condition, and whereby the same may be controlled or carried while in operative condition, substantially in the manner and for the purpose described.

3. A perambulator or carrier comprising a receptacle, wheels, means whereby said receptacle may be carried, or controlled when wheeling, and pockets or guards adapted to inclose the wheels for the purpose herein specified.

4. A receptacle mounted on wheels, means for controlling or carrying said receptacle, and pockets or guards wherein the wheels may be inclosed, substantially in the manner and for the purpose described.

5. A perambulator or carrier consisting of a receptacle provided with a seat, wheels suitably mounted and connected with said receptacle, guards for said wheels, and means whereby the perambulator may be thrown

into wheeling condition, and controlled, or vice versa and carried, substantially in the manner and for the purpose described.

6. A perambulator or carrier, consisting of a receptacle mounted on wheels, means for controlling or carrying said receptacle, guards adapted to inclose the wheels, and mechanism whereby the relative position of the parts may be varied, substantially in the manner set forth and described.

7. A perambulator comprising a basket having a seat, wheels arranged below said basket, mechanism slidably connected with said basket whereby the perambulator is controlled and the position of the wheels regulated, pockets on said basket into which the wheels may be drawn, substantially as and for the purpose described.

8. A perambulator or baby-carriage comprising a basket with a rigid handle, pockets on said basket, wheels adjustably secured to said basket, with mechanism for locking the wheels in their adjusted position, and a second handle loosely secured to the basket whereby the perambulator may be propelled, substantially as and for the purpose described.

9. A perambulator or baby-carriage, consisting of a basket formed to provide a seat therein, and having a rigid or auxiliary handle, pockets formed on the lower end of said basket, wheels adjustably secured to said basket and adapted to be drawn into said pockets, means for locking the wheels in their adjusted position, and a handle loosely secured to said basket adapted to be thrown at any angle to said basket, mechanism for locking said handle in the desired position, and slots in the pockets through which the ends of said handle may pass, substantially as shown and for the purpose described.

10. A perambulator or baby-carriage comprising a basket with a rigid handle, pockets on said basket, wheels secured to hangers having slidable connection with the basket, mechanism for locking the hangers in the desired position, and a second handle loosely secured to the basket and having connection with the hangers whereby the position of the hangers may be changed and the perambulator propelled, substantially as shown and in the manner described.

700,898. CULINARY VESSEL. LEVI ANGLER, Lebanon, Pa. Filed Nov. 12, 1891. Serial No. 81,971. (No model.)

Claim.—A horizontally-closed culinary vessel having a smooth end on its upper end forming one member of a right joint, a rubber adjacent

shorter, and an external concentric projection adjacent to said end and inclined on its lower edge; in combination with a cover having a seat forming the opposite member of said joint, an annular projection engaging said rib on the vessel, and legs projecting from the cover and engaging the inclined edge of said concentric projection.

700,399. PROCESS OF ELECTRICALLY PULVERIZING METALS. PAUL BART, Paris, France. Filed Apr. 11, 1901. Serial No. 88,318. (No specimen.)

Claim.—1. A process for pulverizing metals, which consists in first, causing the metal to flow in streams, then passing electric currents through the length thereof, and then breaking said streams at a point in the flow traversed by the electric current to enable the current to act on the metal on each break of the circuit, substantially as described.

2. A process for pulverizing metals, which consists in melting the metal, causing the same to flow in streams, passing currents of electricity through said streams of sufficient intensity to contract said streams until the same are completely cut off to enable the currents to act on the metal on each break of the circuit, substantially as described.

700,400. BRAKE. FREDERICK BUCKER, New York, N. Y. Filed Sept. 3, 1901. Serial No. 74,008. (No model.)

Claim.—1. The combination of a brake, a socket-piece mounted thereon to carry a handle, an extension-piece projected forward from the socket-piece, a guide forward at the front end of the extension-piece, and a camper adjustably held in the guide.

2. The combination of a brake, a guide held thereby, and a bar adjustably fitted in the guide, said bar having its ends projected beyond the guide, for the purpose specified.

700,401. SPEED-REGULATOR FOR EXPLOSIVE-ENGINE. EDWARD A. F. BRADY, Lansing, Mich. Filed July 10, 1901. Serial No. 66,398. (No model.)

Claim.—1. In an engine, the combination with the exhaust-valve; of a stem for said valve carrying a member of an electrical lighting device, means for holding the valve normally closed and also for holding the members of the igniter in contact, mechanism for imparting a reciprocating and an oscillatory movement to the valve-stem, and a governor operated by excessive speed of the crank-shaft of the engine for holding the valve opened and rendering the igniter inactive.

2. In an engine, the combination with the exhaust-valve and crank-shaft; of pivotally-mounted segments rotatable with the crank-shaft, a centrifugal governor-arm for operating the segments, a rocker-arm actuated by said segments, a catch carried by rocker-arm and another catch on the exhaust-valve stem with which the first-named catch is adapted to engage for holding the exhaust-valve open.

3. In an engine, the combination with the exhaust-valve, exhaust-valve stem and crank-shaft; of a pair of segments embracing the crank-shaft and rotatable therewith, said segments having an interlocking engagement with each other as to move them in more simultaneously outward or inward, a centrifugal governor-arm operatively connected with one of the segments, a rocker-arm having a portion thereof arranged in the path of the segments, a catch carried by said governor-arm, and a governor-catch adapted to cooperate therewith and mounted on the exhaust-valve stem.

governor-catch adapted to cooperate therewith and mounted on the exhaust-valve stem.

4. In an engine, the combination with the exhaust-valve, exhaust-valve stem and crank-shaft; of semicircular segments pivotally mounted on and rotatable with the crank-shaft, said segments having an interlocking engagement at one side of the crank-shaft and a yielding connection at the opposite side of the crank-shaft, a centrifugal governor-arm rotatable around the crank-shaft and operatively connected with one of the segments, a rocker-arm actuated by the segments and carrying a catch, and a governor-catch on the exhaust-valve stem adapted to cooperate with the catch on the rocker-arm.

5. In an engine, the combination with the exhaust-valve, exhaust-valve stem and crank-shaft; of a pair of segments embracing the crank-shaft and rotatable therewith, said segments being pivotally mounted and having an interlocking engagement at one end, a yield-spring yieldingly connecting the opposite ends of the segments, a rocker-arm having a portion thereof arranged in the path of the segments, a catch on said arm, a governor-catch coacting therewith and carried by the exhaust-valve stem, a governor-arm a resistance-spring associated with the governor-arm, and means for adjusting the tension of said spring.

700,402. GAS-REGULATOR. WILLIAM F. BENTON, Broomfield, Iowa. Filed Nov. 20, 1901. Serial No. 61,610. (No model.)

Claim.—1. A tubular regulator, consisting of one piece of sheet metal the longitudinal edges of which are united together.

2. A gas-regulator comprising a structure tubular throughout its entire length, consisting of one piece of sheet metal the longitudinal edges of which are brought in contact and united together and having the side bearings pressed from and made integral therewith.

3. A gas-regulator comprising a structure made of a single plate of sheet metal, tubular throughout its entire length, the longitudinal edges of which are brought in contact and united together and having the side bearings pressed from and made integral therewith.

4. A gas-regulator comprising a true-shape structure, tubular throughout its entire length, consisting of a single piece of sheet metal the longitudinal edges of which are brought in contact and united together.

5. A gas-regulator comprising a structure, tubular throughout its entire length, consisting of a single piece of sheet metal the longitudinal edges of which are brought in contact and united together and having the central bearing-plate pressed from and made integral therewith.

6. A gas-regulator comprising a structure made of a single plate of sheet metal the longitudinal edges of which are brought in contact and united together and tubular throughout its entire length, and having a central bearing-plate pressed from and made integral therewith.

7. A gas-regulator comprising a structure, tubular throughout its entire length consisting of a single piece of sheet metal the longitudinal edges of which are brought in contact and united together and having the side bearings made integral therewith.

8. A gas-regulator comprising a structure made of a single plate of sheet metal the longitudinal edges of which are brought in contact and united together and tubular throughout its entire length, and having side bearings pressed from and made integral therewith.

9. A gas-regulator comprising a structure, tubular throughout its entire length consisting of a single plate of sheet metal the longitudinal edges of which are brought in contact and united together and having the truck-column guides pressed from and made integral therewith.

10. A gas-regulator comprising a structure made of a single plate of sheet metal, the longitudinal edges of which are brought in contact and united together and tubular throughout its entire length, and having a truck-column guide pressed from and made integral therewith.

11. A gas-regulator comprising a structure tubular throughout its entire length, consisting of a single plate of sheet metal having the longitudinal edges thereof brought in contact and united together and having the central bearing-plate, the side bearings, and the truck-column guides thereof made integral therewith.

12. A gas-regulator comprising a structure made of a single plate of sheet metal, the longitudinal edges of which are brought in contact and united together and tubular throughout its entire length, and having a central bearing-plate, side bearings and truck-column guides pressed from and made integral therewith.

13. A gas-regulator comprising a true-shape structure, tubular throughout its entire length consisting of a single plate of sheet metal the longitudinal edges of which are brought in contact and united together and having the central bearing-plate the side bearings, and the truck-column guides thereof made integral therewith.

14. A gas-regulator comprising a true-shape structure, made of a single plate of sheet metal the longitudinal edges of which are brought in contact and united together and tubular throughout its entire length, and having a central bearing-plate, side bearings, and truck-column guides pressed from and made integral therewith.

700,403. GAS-PRESSURE REGULATOR. DAVID L. BARK, New York, N. Y., assignor of one-half to Jacob Lederer, New York, N. Y. Filed Feb. 7, 1902. Serial No. 61,651. (No model.)

Claim.—1. A gas-regulator composed of a flexible tubular casing having a dilated transversely-extending base and a dilated transversely-extending head, to form two sets of outwardly-opening valves, substantially as specified.

2. A gas-regulator composed of a flexible tubular casing having a flat radially-dilated base and a bulged radially-dilated head, to form two sets of outwardly-opening valves, substantially as specified.

700,404. DOOR-OPERATING MECHANISM. WILLIAM A. BRADY and JAMES S. BRADY, Chicago, Ill., assignors to the Braden Supply & Repair Company, Chicago, Ill., a Corporation. Filed Nov. 6, 1900. Serial No. 738,585. (No model.)

Claim.—1. In apparatus of the character described, the combination of two oppositely-arranged, open-ended cylinders, pistons within said cylinders rigidly connected together by a common piston-rod, an operating connection for a door or device to be shifted, secured at one end to said piston-rod intermediate said pistons, and a valve common to both of said cylinders for controlling the alternate admission of fluid under pressure thereto.

2. In apparatus of the character described, the combination of two oppositely-arranged, open-ended cylinders, pistons within said cylinders rigidly connected together by a common piston-rod, an operating connection for a door or device to be shifted, secured at one end to said piston-rod intermediate said pistons, an admission and exhaust channel for each of said cylinders and a valve common to both cylinders for controlling the alternate admission and exhaust of fluid under pressure through said channels.

3. In apparatus of the character described, the combination with a suitable part, such for example as a cross-head, adapted to be connected with the door or device to be shifted, of oppositely-arranged pistons connected to said part or cross-head, cylinders wherein said pistons are contained, suitable casings at the ends of said cylinders provided with admission and exhaust channels and a bellows rod extending between said casings, substantially as described.

4. In apparatus of the character described, the combination with a suitable part, such for example as a cross-head, adapted to be connected with the door or device to be shifted, of pistons connected to said part or cross-head, cylinders wherein said pistons are contained, suitable channels for delivering fluid under pressure to said cylinders, escape-channels for exhausting fluid from said cylinders and adjustable throttling-valves for regulating the flow through said exhaust-channels.

5. In apparatus of the character described, the combination of two oppositely-arranged, open-ended cylinders, pistons within said cylinders rigidly connected together by a common piston-rod, an operating connection for a door or device to be shifted, secured at one end to said piston-rod intermediate said pistons, the outer ends of said cylinders being provided with ports for the admission and exhaust of fluid under pressure, a valve-chamber having inlet and exhaust passages, channels leading from said valve-chambers to the ports of each of said cylinders, and a valve in said chamber for controlling the flow of fluid under pressure through said channels.

6. In apparatus of the character described, the combination with a suitable part, such for example as a cross-head, adapted to be connected with the door or device to be shifted, of pistons connected to said part or cross-head, cylinders wherein said pistons are contained, admission and

exhaust channels for delivering fluid under pressure to said cylinders, hollow piston-rods whereby said pistons are carried, hollow plugs extending into the cylinders and adapted to enter the piston-rods and suitable connections between said hollow plugs and the exhaust-channels, substantially as described.

7. In apparatus of the character described, the combination with a suitable part, such for example as a cross-head, adapted to be connected with the door or device to be shifted, of oppositely-arranged open-ended cylinders, pistons within said cylinders having piston-rods connected with said part or cross-head, a casing at the outer end of each of said cylinders provided with admission and exhaust channels, a tubular rod connecting said casings, a valve for controlling the flow of fluid under pressure to and from said cylinders and a trigger for operating said valve, substantially as described.

8. In apparatus of the character described, the combination with a suitable part, such for example as a cross-head, adapted to be connected with the door or device to be shifted, of pistons on either side of and connected to said part or cross-head, single-acting cylinders wherein said pistons are contained, admission and exhaust channels for delivering fluid under pressure to and from each of said cylinders, a valve-chamber provided with a casing to which the admission and exhaust channels lead, a valve common to both of said cylinders for controlling the flow of fluid under pressure through said channels, and a valve-rod and means for shifting said rod to operate said valve, substantially as described.

9. In apparatus of the character described, the combination with a suitable part, such for example as a cross-head, adapted to be connected with the door or device to be shifted, of pistons connected to said part or cross-head, cylinders wherein said pistons are contained, admission and exhaust channels for delivering fluid under pressure to and from said cylinders, a valve-chamber provided with a casing to which the admission and exhaust channels lead, a valve for controlling the flow of fluid under pressure through said channels, a valve-rod connected to said valve, a cylinder through which said valve-rod passes, said cylinder being connected by a suitable channel with the fluid-pressure supply and a piston within said cylinder connected to the valve-rod, substantially as described.

10. In apparatus of the character described, the combination with a suitable part, such for example as a cross-head, adapted to be connected with the door or device to be shifted, of pistons on either side of and connected to said part or cross-head, single-acting cylinders wherein said pistons are contained, admission and exhaust channels for delivering fluid under pressure to and from said cylinders, a valve-chamber provided with a casing to which the admission and exhaust channels lead, a valve common to both of said cylinders for controlling the flow of fluid under pressure through said channels, a valve-rod connected to said valve, a trigger attached to said valve-rod, suitable bearings for said valve-rod and suitable stops upon said rod, substantially as described.

11. In apparatus of the character described, the combination with a suitable part, such for example as a cross-head, adapted to be connected with the door or device to be shifted, of pistons connected to said part or cross-head, cylinders wherein said pistons are contained, a casing at the outer end of each of said cylinders provided with admission and exhaust channels for delivering fluid under pressure to and from said cylinders, one of said casings being provided with a valve-chamber having a valve therein and a removable valve-rod attached to said casing, substantially as described.

12. In apparatus of the character described, the combination with a suitable part, such for example as a cross-head, adapted to be connected with the door or device to be shifted, of pistons connected to said part or cross-head, hollow rods whereby said pistons are carried, cylinders wherein said pistons are contained, casings at the outer ends of said cylinders provided with admission and exhaust channels and hollow plugs extending through said casings and adapted to enter said hollow piston-rods, said hollow plugs being provided with ports communicating with the exhaust-channels, substantially as described.

13. In apparatus of the character described, the combination with a cylinder and a piston therein adapted to operate a door or other device to be shifted, of channels for the admission and exhaust of fluid under pressure to and from said cylinder, a valve-chamber, a valve therein for controlling the flow through said channels, and a valve-rod removably secured to said valve-chamber, said valve-rod having passages therein connecting said valve-chamber to said channels.

14. In a door-operating device, the combination of a cylinder, a piston therein for actuating a door or other device to be shifted, two ports opening into one end of said cylinder, means for closing one of said ports during the exhaust-stroke of the piston and an adjustable throttling-valve for the other of said ports, whereby the movement of the shifted part will be controlled.

15. In a door-operating device, the combination of a cylinder, a piston therein for actuating a door or other device to be shifted, two ports opening into one end of said cylinder, outwardly-closing check-valve for

one of said ports for closing the latter during the exhaust-stroke, whereby the movement of the shifted part will be controlled.

16. In a door-operating device, the combination with the cylinder and a piston therein for actuating a door or other device to be shifted, of two ports opening into said cylinder through which the motor fluid escapes during the exhaust-stroke of said piston, one of said ports arranged to be closed before the piston has completed its exhaust-stroke, whereby the movement of the shifted part will be controlled.

17. In a door-operating device, the combination with the cylinder and a piston therein for actuating a door or other device to be shifted, of two ports opening into said cylinder through which the motor fluid escapes during the exhaust-stroke of said piston, one of said ports being mounted on the end of a tubular extension within said cylinder, a hollow piston-rod for said piston into which said extension enters, the other of said ports opening into the end of said cylinder and provided with an adjustable throttling-valve, whereby the movement of the shifted part will be controlled.

18. In a door-operating device, the combination with the cylinder and a piston therein for actuating a door or other device to be shifted, of two ports opening into said cylinder through which the motor fluid escapes during the exhaust-stroke of said piston, one of said ports being mounted on the end of a tubular extension within said cylinder, a hollow piston-rod for said piston into which said extension enters, the other of said ports opening into the end of said cylinder and provided with an adjustable throttling-valve, whereby the movement of the shifted part will be controlled.

19. In a shifting device for doors and the like, the combination with a cylinder and a piston therein, of three ports opening into one end of said cylinder, one of said ports provided with an outwardly-closing check-valve for closing the latter during the exhaust-stroke of the piston, means for closing another of said ports before the piston has completed its exhaust-stroke, whereby the escape of the motor fluid during the last part of the exhaust-stroke will only take place through the remaining port.

20. In a shifting device for doors and the like, the combination with duplicate cylinders and pistons therefor, of three ports opening into the outer ends of each of said cylinders, one of the ports of each of said cylinders being provided with an outwardly-closing check-valve for closing the latter during the exhaust-stroke of the piston therein, another of said ports in each of said cylinders being located intermediate to said check-valve and arranged to be closed by the piston therein before it has completed its exhaust-stroke, and the remaining port in each cylinder being provided with an adjustable throttling-valve, whereby the movement of the part to be shifted in each direction will be controlled.

21. In a shifting device for doors and the like, the combination with duplicate, single-acting cylinders and pistons therein rigidly connected together by a common hollow piston-rod, of three ports opening into the outer ends of each of said cylinders, one of the ports in each cylinder being provided with an outwardly-closing check-valve, another of said ports being mounted upon the inner end of tubular extension within said cylinders, said extensions being adapted to enter said hollow piston-rod, and the remaining port in each cylinder being provided with an adjustable throttling-valve, whereby the movement of the part to be shifted in both directions will be controlled.

22. In a shifting device for doors and the like, the combination with a cylinder and a piston therein, a valve-chamber, a valve therein controlling the admission and exhaust of fluid under pressure to and from said cylinder, a valve-rod therefor, a chamber surrounding said rod, and a piston within said chamber secured to said rod, there being an opening leading from said valve-chamber to said piston-chamber, whereby the valve is automatically operated in one direction by the fluid-pressure.

700,405. ACETYLENE-GAS-GENERATING APPARATUS. FRIEDRICH DUCHER, Mannheim, Germany. Filed May 3, 1902. Serial No. 14,102. (No model.)

Claim.—1. In the improved acetylene-gas-generating apparatus, the combination with a water-tank and a shaft journaled in walls of said tank, of a series of carriers loosely mounted on said shaft, having holes in their upper ends and adapted to receive a series of interchangeable carbide-holders, another shaft journaled above the first-mentioned shaft, a series of suitable catches on the upper shaft arranged to engage the holes in said carriers and to be successively disengaged therefrom by the rotating of said shaft, means for actuating the upper shaft during the down movement of the gas-holder, and means for raising the carbide-holders after the operation, substantially as set forth.

2. In the improved acetylene-gas-generating apparatus, the combination with a water-tank and an inclined partition extending downwardly from the top of said tank and forming a gas-collecting head, of a shaft journaled in the walls of the latter, a series of carriers loosely mounted on said shaft, having holes in their upper ends and adapted to receive carbide-holders, a second shaft journaled above the partition, a series of curved

catches progressively increasing in length and arranged on said upper shaft and engaging the holes in the loosely-mounted carriers, a bridged rotating-rod secured on the first-mentioned shaft and upon which drop the levers in operation, means for rotating the lever-carrying shaft, and means for transmitting the down movement of the gas-holder to the upper shaft, substantially as set forth.

700,406. HYDRAULIC DREDGE. GEORGE L. COOPER, New York, N. Y. Original application filed June 3, 1901, Serial No. 62,502. Divided and this application filed Aug. 23, 1902. Serial No. 73,392. (No model.)

Claim.—1. In a dredge, excavator and elevator, a stand-pipe comprising a head-section, an injector-section, an intermediate section, and a discharge-pipe having an outlet therefrom, and a supplemental tubular section projected above the outlet in the discharge-pipe, substantially as set forth.

2. A dredge, excavator and elevator comprising a stand-pipe, a suitable shaft, two horizontally-located pipes communicating at their lower ends with the stand-pipe and rigidly secured to the stand-pipe at their upper ends, a suitable support and means for adjustingly rotating the stand-pipe to the support comprising guide-bushes through which the stand-pipe are fixed to slide, substantially as set forth.

3. In combination, a dredging, excavating and elevating apparatus

and means for adjusting it comprising a suitable framework, a cross-shaft mounted therein, a sprocket-wheel fixed on the shaft, a counterbalance-weight, a chain passing over the said sprocket and connecting the counterbalance-weight with the apparatus, a large sprocket fixed on said cross-shaft, a small sprocket having an operating crank-handle and a sprocket-chain connecting the last-named two sprockets, substantially as set forth.

700,407. MINER'S SAFETY-LAMP. ARMA H. BARKS and FRANK E. BARKS, Scranton, Pa. Filed July 13, 1902. Serial No. 24,117. (No model.)

Claim.—The herein-described magnetic locking device for miner's lamps consisting in combination with the bowl of said lamp, of a chamber in one side of said bowl, a spring-controlled sliding pin within said chamber, one end of said pin projecting upward and arranged to engage with a recess in the body of the lamp to which the said bowl is to be attached for the purpose of locking it therein, and the other end of said pin provided with a comparatively large-diameter armature lengthened so as to cover both poles of a horseshoe-magnet and slidable within the chamber, the bottom of said chamber provided with a suitable closure, whereby the sliding pin may be drawn downward by the action of an electromagnet when the lamp is placed in close relation to such magnet, for the purpose of disengaging the locking device, and at the same time preventing any physical contact with the armature or pin from without, substantially as specified.

700,408. TIDAL MOTOR. EDWARD W. DUNSTON, Englewood, England. Filed Mar. 10, 1902. Serial No. 97,495. (No model.)

Claim.—1. In a device of the character described, a wheel, rings carried by the wheel and adjustable thereon, and buckets mounted in the wheel and rings.

2. In a device of the character described, a wheel, a ring carried by the wheel and adjustable thereon, and buckets pivoted in the ring and loosely seated on the wheel.

3. In a device of the character described, a wheel, rings adjustable thereon, buckets pivoted in the rings and angle-strips on the periphery of the wheel between which the ends of the buckets are loosely held.

4. In a device of the character described, a wheel having a flat periphery with an annular flange on its inner side, a ring on each side of the periphery, cross-bars connecting the rings and slidably bearing on the flange, buckets pivoted to the rings and loosely seated on the periphery of the wheel, and means for adjusting the rings on the wheel.

5. In a tidal motor, a raft or divided barge, an underfoot wheel mounted thereon, buckets carried by the wheel and means for discharging the water from the bottom of all of the buckets of the wheel.

700,409. MICROSCOPE. SAMUEL V. BERNHARD, Buffalo, N. Y., assignor to Spencer Lens Company, Buffalo, N. Y. Filed Sept. 4, 1901. Serial No. 74,885. (No model.)

Claim.—1. In a microscope, the combination with a substage-arm movable toward and from the optical axis of the instrument, of illuminating device pivotedly connected with said substage-arm so as to swing in a plane substantially at right angles to that of the arm, substantially as set forth.

2. In a microscope, the combination with a substage-arm movable toward and from the optical axis of the instrument, of a diaphragm pivotedly connected to said arm, and a condenser pivotedly connected to said arm so as to swing in a plane substantially at right angles to that of the arm, substantially as set forth.

3. In combination, a dredging, excavating and elevating apparatus

3. In a microscope, the combination with a stage, and a substage-arm movable toward and from the optical axis of the instrument and toward and from said stage, of illuminating device pivotally connected to said arm so as to swing in a plane substantially at right angles to that of the arm, substantially as set forth.

4. In a microscope, the combination with a substage-arm movable toward and from the optical axis of the instrument, of a diaphragm carried by said arm, and an illuminating device pivotally connected to said arm so as to swing in a plane substantially at right angles to that of the arm, substantially as set forth.

5. In a microscope, the combination with a substage-arm movable in a horizontal plane toward and from the optical axis of the instrument, of a separate frame secured to said arm, and an illuminating device pivotally connected to said frame, substantially as set forth.

6. In a microscope, the combination with a substage-arm movable toward and from the optical axis of the instrument, of a separate frame secured to said arm, a diaphragm pivotally connected to said frame, and a condenser pivotally connected to said frame, substantially as set forth.

7. In a microscope, the combination with a substage-arm having a ring-shaped part, of a frame supported on said part and having a flange extending down through the opening thereof, a diaphragm secured to said flange, a diaphragm pivotally connected to said frame, and a condenser pivotally connected to said frame, substantially as set forth.

8. In a microscope, the combination with a substage-arm movable toward and from the optical axis of the instrument, of a condenser pivotally connected thereto, and a diaphragm pivotally connected to said arm and adapted to be swung over said condenser concentric therewith, substantially as set forth.

9. In a microscope, the combination of a stage, a substage-arm connected with the stage by a vertical pivot to swing laterally toward and from the optical axis of the instrument, a condenser, and a diaphragm connected to opposite sides of said arm by horizontal pivots to swing in a vertical plane over the arm toward and from a position concentric with the optical axis, substantially as set forth.

700,410. PIPAL-PUMP OUT-OUT. CHARLES J. DORRIS, Salt Lake, Utah. Filed Oct. 12, 1901. Renewed Oct. 14, 1901. Serial No. 71,501. (No model.)

Claim.—1. In an electric cut-out, a series of fins, a bar normally connected to each fin, a second bar adapted to be connected with any

fin at will, a key for effecting said connection, a one provided with a series of lugs, and a series of blocks adjustably positioned for the attachment of the fins, non-conducting fins situated in a direct line between the ends of the fins and said bars, said conductive blocks being provided with grooves to receive the fins, and non-conducting material separating the blocks.

2. In an electric cut-out, a series of fins, a bar normally connected to each fin, a series of fins, means for putting said fins in direct connection, a rib situated in one part and adapted to prevent transportation of metal upon the bearing out of a fin, and a groove corresponding to the rib situated in the other part of the bar, the rib being seated in the groove when the parts are closed.

3. In an electric cut-out, a series of fins, a bar normally connected to each fin, a second bar adapted to be connected with any fin at will, a key for effecting said connection, conductive blocks or parts adjustably positioned for the attachment of the fins, non-conducting fins between the blocks and said bars, and non-conducting elements between said blocks, said elements extending from one of the bars to the other.

4. In an electric cut-out, a series of fins, a bar normally connected to each fin, a second bar adapted to be connected with any fin at will, a key for effecting said connection, conductive blocks or parts adjustably positioned for the attachment of the fins, non-conducting fins between the blocks and said bars, and non-conducting elements between said blocks, said elements extending from one of the bars to the other.

700,411. HAND-SAW. RICHARD F. DOWNEY, Milwaukee, Wis., assignor to the Automatic Portable Sawing Alloy Company, Milwaukee, Wis. Filed Aug. 17, 1901. Serial No. 71,502. (No model.)

Claim.—A hand-saw, provided for the reception of the thumb and finger of the user, in combination with pivoted spring-controlled flaps for closing the same.

700,412. SLITCH. RAY E. FISHER, East Orange, N. J. Filed Sept. 24, 1901. Serial No. 71,503. (No model.)

Claim.—1. The combination with a stationary member, of a carrier movable longitudinally relative to said stationary member, a gripping device carried by said carrier and movable transversely of the line of movement of the carrier, and a part on said stationary member for moving said gripping device transversely, substantially as set forth.

2. The combination with a casing having an inclined face, of a carrier in said casing, a spring for moving the same in one direction, an operating device for moving the same against the action of said spring, and a gripping device carried by said carrier and moved by said inclined face transversely of the line of movement of said carrier, substantially as set forth.

3. The combination with a casing having a hole in one end and an inclined face, of a spring-powered carrier in said casing having a bar or bar in alignment with the hole in the end of the casing, said bar being in contact with said hole, gripping device carried by said bar and working on said inclined face, and an operating part for said carrier, substantially as set forth.

4. The combination with a casing having a hole in one end and a central internal face, of a carrier in said casing having a bar or bar in alignment with the hole in the end of the casing and a part extending with said bar, an operating device for said carrier projecting through an opening in the opposite end of the casing and having a hole aligned with

the bore in the carrier, and a coil-spring surrounding said stem and confined between the carrier and the end of the casing, substantially as set forth.

700,413. SELF-PLAYING INSTRUMENT. BLAISEN E. FISHER, Chicago, Ill., assignor to Fortuna Organ Company, Detroit, Mich., a Corporation of Michigan. Filed Nov. 24, 1901. Serial No. 71,504. (No model.)

Claim.—1. The combination with the main-chest and tracker-range of a self-playing instrument or playing attachment, of means adapted to be put in operation while playing automatically and serving to prevent the air from entering the range-passages when they are uncovered by the perforations in the main-chest, substantially as specified.

2. The combination with the main-chest and tracker-range of a self-playing instrument or playing attachment, of means operable by hand while playing automatically and serving to prevent the air from entering the range-passages when they are uncovered by the perforations in the main-chest, substantially as specified.

3. The combination with the main-chest and tracker-range of a self-playing instrument or playing attachment, of means for controlling different tracker-range openings and adapted to be positioned against the chest and over the tracker-range during the automatic playing, and thus to enclose the air from the range or any portion or portions thereof desired, substantially as specified.

4. The combination with the main-chest and tracker-range of a self-playing instrument or playing attachment, of a series of means adapted to be positioned at will over the tracker-range and each covering and enclosing the air from a plurality of the range-passages, substantially as specified.

5. The combination with the main-chest and tracker-range of a self-playing instrument or playing attachment, of means for enclosing the air from the tracker-range passages when uncovered by the perforations of the chest, such means being operable by finger-keys, substantially as specified.

6. The combination with the main-chest and tracker-range of a self-playing instrument or playing attachment, of means operable by finger-keys for enclosing the air from the range-passages when uncovered by the chest, and an inner cover for the chest and its rollers, acting also to support said keys, substantially as specified.

7. The combination with the main-chest and tracker-range of a self-playing instrument or playing attachment, of means for sealing portions of the tracker-range, and an inner cover 11 by which said means are supported, substantially as specified.

8. The combination with the main-chest and tracker-range of a self-playing instrument or playing attachment, of means for sealing portions of the tracker-range, and a hinged inner cover by which the said means are supported and moved out of the way when changing the chords, substantially as specified.

9. The combination in a self-playing instrument or playing attachment, of a main-chest, main-chest rollers and tracker-range located in a well in the instrument or attachment, an outer cover for closing the well when the instrument or attachment is not being used, an inner cover for the well adapted to support the rollers made by the rollers, and sealing device supported by said cover and acting to seal portions of the range, substantially as specified.

700,414. FRISHER AND BELLS SEVEN FOR FORTY-THREE AND CAMELBACK MACHINES. JAMES FRISHER, Worcester, R. I. Original application filed Jan. 28, 1901. Serial No. 61,699. Divided and this application filed Apr. 1, 1901. Serial No. 71,505. (No model.)

Claim.—1. In combination, the printing-roll, the taking-roll, a carrier for said taking-roll, means to press the taking-roll toward the printing-

roll, a cam rotating in unison with the printing-roll, a movable member intermediate the surface of said cam and said carrier, means to hold said member in continuous contact with the surface of said cam while the taking-roll is in contact with the printing-surface of the printing-roll, and a yielding cushion between said carrier and movable member to relieve the shock when the two come together after being separated, substantially as described.

2. In combination, the printing-roll, the taking-roll, a carrier for said taking-roll, means to press the taking-roll toward the printing-roll, a cam rotating in unison with the printing-roll, a movable member intermediate the surface of said cam and said carrier, a spring interposed between said carrier and said movable member and operating to hold said member in continuous contact with the surface of said cam while the taking-roll is in contact with the printing-surface of the printing-roll, and a yielding cushion between said carrier and movable member to relieve the shock when the two come together after being separated, substantially as described.

3. In combination, the printing-roll, the taking-roll, a carrier for said taking-roll, means to press the taking-roll toward the printing-roll, a cam rotating in unison with the printing-roll, a movable member intermediate the surface of said cam and said carrier, means to hold said member in continuous contact with the surface of said cam while the taking-roll is in contact with the printing-surface of the printing-roll, a yielding cushion between said carrier and movable member to relieve the shock when the two come together after being separated, and means to adjust the said cushion in the plane of movement of the carrier and movable member, substantially as described.

4. In combination, the printing-roll, the taking-roll, a carrier for said taking-roll, means to press the taking-roll toward the printing-roll, a cam rotating in unison with the printing-roll, a movable member intermediate the surface of said cam and said carrier, a spring interposed between said carrier and said movable member and operating to hold said member in continuous contact with the surface of said cam while the taking-roll is in contact with the printing-surface of the printing-roll, a yielding cushion between said carrier and movable member to relieve the shock when the two come together after being separated, and means to adjust the said cushion in the plane of movement of the carrier and movable member, substantially as described.

5. In combination, the printing-roll, a cam rotating in unison therewith, the taking-roll, an arm carrying the said taking-roll, an arm operated by the said cam, a yielding cushion between the two arms, and a spring tending to separate the two arms, substantially as described.

6. In combination, the printing-roll, a cam rotating in unison therewith, the taking-roll, an arm carrying the said taking-roll, an arm operated by the said cam, a yielding cushion between the two arms, means to adjust the said cushion in the plane of the two arms, and a spring tending to separate the two arms, substantially as described.

700,415. AUTOMATIC BRAKE AND POWER-SHIFTING MECHANISM. JOHN F. GARR, Kansas, Wis., assignor to the Kansas Manufacturing Company, Kansas, Wis., a Corporation of Wisconsin. Filed Aug. 28, 1901. Serial No. 71,506. (No model.)

Claim.—1. The combination with a shaft and a wheel fixed immovably upon said shaft, of mechanism for applying power to said wheel, mechanism for shifting said two-continued mechanism, and a brake normally held out of engagement with a periphery which is in working relation with said shaft and arranged to operate said shifting mechanism when said brake moves into action, the portion of said brake between its support and said periphery being of increasing thickness, substantially as described.

2. The combination with a shaft and a power-pulley and an idle pulley mounted upon said shaft, of belt-shifting mechanism and brake mechanism normally held out of engagement with said power-pulley, and adapted to actuate said belt-shifting mechanism when said brake mechanism moves into action, the portion of said brake between its support and said periphery being of increasing thickness, substantially as described.

3. The combination with a shaft and a wheel fixed immovably upon said shaft, of mechanism for applying power to said wheel, mechanism for shifting said last-mentioned mechanism, and a brake normally held out of engagement with a periphery which is in working relation with said shaft and arranged to actuate said shifting mechanism when said brake moves into action, and electric mechanism for releasing said brake, substantially as described.

4. The combination with a shaft and a power-pulley and an idle pulley mounted upon said shaft, of belt-shifting mechanism and brake mechanism normally held out of engagement with said power-pulley, and arranged to actuate said belt-shifting mechanism when said brake mechanism moves into action, and electric mechanism for releasing said brake, substantially as described.

5. The combination with a shaft and a wheel fixed immovably upon said shaft, of mechanism for applying power to said wheel, mechanism for shifting said last-mentioned mechanism, and a brake normally held out of engagement with a periphery which is in working relation with said shaft and arranged to actuate said shifting mechanism when said brake moves into action, the portion of said brake between its support and said periphery being of increasing thickness, and means for manually shifting the support of said brake mechanism away from said periphery, when said brake is to be reset, substantially as described.

6. The combination with a shaft and a power-pulley and an idle pulley mounted upon said shaft, of belt-shifting mechanism and brake mechanism normally held out of engagement with said power-pulley, and adapted to actuate said belt-shifting mechanism when said brake mechanism moves into action, the portion of said brake between its support and said periphery being of increasing thickness, and means for manually shifting the support of said brake mechanism for the purpose of releasing and resetting said brake, substantially as described.

7. The combination with a shaft and a wheel fixed immovably upon said shaft, of mechanism for applying power to said wheel, mechanism for shifting said last-mentioned mechanism, and a brake normally held out of engagement with a periphery which is in working relation with said shaft and adapted to actuate said shifting mechanism when said brake moves into action, and electric mechanism for releasing said brake, and means for manually shifting the support of said brake mechanism away from said periphery, when said brake is to be reset, substantially as described.

8. The combination with a shaft and a power-pulley and an idle pulley mounted upon said shaft, of belt-shifting mechanism and brake mechanism normally held out of engagement with said power-pulley, and arranged to actuate said belt-shifting mechanism when said brake mechanism moves into action, and electric mechanism for releasing said brake, and means for manually shifting the support of said brake mechanism for the purpose of releasing and resetting said brake, substantially as described.

9. The combination with a wheel or pulley, A, of an eccentric brake, a relatively fixed shaft supporting said brake, a spring tending to move said brake into action, an armature making reliable engagement with said brake for holding the latter out of action against the force of said spring, and electromagnets for shifting said armature, and a belt-shifter located in suitable relation to said brake to be actuated when the latter moves into action, substantially as described.

10. The combination with a shaft, A², and a fixed and a loose pulley located thereon, of a belt-shifting mechanism comprising a belt-crank,

and a brake having a shoe held normally out of engagement with said power-pulley and placed in suitable relation with one arm of said belt-crank to actuate the latter when said brake-shoe is moved into action, substantially as described.

11. The combination with power-shifting mechanism and brake mechanism arranged in suitable relation to each other, of electric mechanism for controlling said brake mechanism, and an automatic switch for reversing the condition of said electric mechanism, when said shifting mechanism and said brake mechanism have been actuated, substantially as described.

12. The combination with power-shifting mechanism and brake mechanism arranged in suitable relation to each other, of electric mechanism for controlling said brake mechanism, and an automatic switch for breaking the circuit upon which said electric mechanism is located, after said power-shifting mechanism and said brake mechanism have been actuated, substantially as described.

13. The combination with the belt-shifting mechanism comprising the yoke, U, bar, O, and links, O', of a brake, a suitable connection between said brake and said bar, and electric mechanism for controlling said brake, and an electric switch suitably coupled to said belt-shifting mechanism, substantially as described.

700,416. TAIL-BOARD FASTENING FOR WAGONS. JOHN R. GRABER, Dubuque, Iowa, assignor of one-half to James G. Allyn, Dubuque, Iowa. Filed Mar. 7, 1902. Serial No. 97,141. (No model.)

Claim.—1. The combination of a wagon-box, tail-board, a chain fastened to the center of said tail-board and provided with over-throwers upon its outer ends, a casing attached to the wagon-box, and a bar within the casing adapted to engage the ends of the chain, for the purpose shown.

2. The combination of a wagon-box, tail-board, a chain fastened to the center of the tail-board and provided on each end with an eyebolt, a casing attached to the wagon-box and formed of the plates I and K and a bar G set within the casing and adapted to engage the eyebolt upon the chain, for the purpose shown.

700,417. LETTER-FILE AND CARRIER. WALLACE S. GRABER, Kirkland, Ill. Filed Oct. 24, 1901. Serial No. 79,606. (No model.)

Claim.—1. The file and cabinet consisting of the cabinet provided with horizontal partitions or strips having depending flaps or guards on the under side thereof, said flaps or guards set back from the outer edges of the horizontal portions, and a number of files each formed with one open side and arranged so that the closed side of one file shall be the open side of the adjoining file, each file having its front end wall extended above its side wall and formed with a shoulder below its top edge so as to have the extended portion bear against the face of the depending flaps or guards and the shoulder to lie below the under side of the depending flaps, substantially as described.

2. A cabinet paper-file having one open side with its front end wall extended above the closed side of the file, means for holding the contents

of the file in place, and a cross-strip extending across the open side of the lower end of the file, the top edge of said strip being below the middle portion of the file, substantially as described.

3. A cabinet paper-file having one open side with a cross piece or strip across its lower portion and a front and a rear wall and open top, its front and rear walls being extended above the closed side of the file, and a frictionally-held swinging clasp or clamp for holding the contents of the file in place, said clasp adapted to be swung over to the rear of the closed side of said file to form a support therefor, substantially as described.

4. A cabinet paper-file having one open side and provided with a swinging resilient clasp or clamp of greater width than the space between the end walls of the file whereby it is adapted to be held in clamping position by frictional contact with a part of the file, said clasp being pivotally secured to the file near its upper portion to adapt it to be swung to the rear of the closed side of the file to constitute a support for holding the file in an inclined position, substantially as described.

5. A cabinet paper-file having one open side and front and rear end walls, the rear end wall having an inclined cut-away portion, and a swinging resilient clasp or clamp adapted to be held in clamping position by frictional contact with a part of the file, a part of said clasp lying adjacent to the inclined cut-away portion of the rear end wall of the file, whereby the finger may be inserted between said part of the clasp and the cut-away portion of the end wall for the purpose of releasing the clasp substantially as described.

6. A cabinet paper-file having one open side and having the upper portion of the closed side slanted, in combination with a swinging clasp or clamp having its side extended at an angle to its ends so as to adapt its ends to lie in the slanted portions of the closed side when the clasp or clamp is swung to the rear of the closed side with the side of the clasp in position to support the file in an inclined position, substantially as described.

7. A cabinet paper-file having an open and a closed side, and means for bearing against the contents of the file to hold them in place, said means being adapted to be swung over to the rear of said closed side to form a support for the file, substantially as described.

8. A cabinet paper-file having one open and a closed side, and a swinging clasp or clamp adapted to be swung over to the rear of the closed side to form a support for the file, said clasp having its side extended at an angle to its ends, and the ends forming a rest for the file when the clasp is swung over to the rear of the closed side of said file, substantially as described.

700,418. PAPER BOX. WALTER S. HAM, Dayton, Ohio. Filed Dec. 18, 1901. Serial No. 65,364. (No model.)

Claim.—1. In a paper box, a corner-lock consisting of slats formed in the sides thereof, a substantially rectangular-shaped locking-flap at each corner intermediate the sides, each flap being diagonally slatted and secured so as to be folded upon itself, threaded through its respective slit in the side and unfolded in the inside of the box, against the bottom and into the corner of the box, forming a combined corner lock and brace, substantially as specified.

2. In a paper box, a corner-lock consisting of slats formed in the sides thereof, a substantially rectangular-shaped locking-flap at each corner intermediate the sides, each flap having a diagonal slit at its inner corner, and a secured line formed on said flap whereby the flap can be doubled upon itself, threaded through its respective slit in the side and unfolded in the inside of the box against the bottom and into the corner of the box, forming a combined corner lock and brace, substantially as specified.

3. In a paper box, a corner-lock consisting of slats formed in the sides thereof, a substantially rectangular-shaped locking-flap at each corner intermediate the sides, each flap being provided with a slit extending through its inner corner toward the middle of the flap and a secured line extending from the end of the slit obliquely toward an adjacent corner of the flap, whereby the secured end of the flap can be folded outwardly upon itself and threaded through its respective slit in the side and unfolded in the inside of the box against the bottom and into the corner of the box, forming a combined corner lock and brace, substantially as specified.

4. In a paper box a corner-lock consisting of slats formed in the sides thereof, a substantially rectangular-shaped locking-flap intermediate the slatted sides, each flap having a slit and a secured line converging inwardly from the base of the locking-flap and terminating at a point of intersection in the middle portion of the flap, whereby the slatted portion of the flap may be folded upon the body of the flap along said secured line, the doubled flap threaded through its adjacent side slit and unfolded upon the interior of the box, forming a corner-lock, substantially as specified.

700,419. ORIENTED SHAP-RENTAL CUTTING, COPIING, AND UPSETTING MACHINES. DAVID HARRISON, Canton, Ohio. Filed Aug. 2, 1902. Serial No. 87,966. (No model.)

Claim.—The combination of a frame provided with a shaft, having located therein a reciprocating plunger, a sliding head connected to the plunger, a plunger connected to the sliding head, the parallel shafts 5 and 13¹ having mounted on said shaft wheels 6 and 12, clutch mechanism for throwing the shafts in and out of gear and means for imparting reciprocating motion to the plunger and to the sliding head, substantially as and for the purpose specified.

700,420. APPARATUS FOR PURIFYING WATER. ARTHUR HANER, London, England. Filed Nov. 14, 1901. Serial No. 62,671. (No model.)

Claim.—1. In a water purifying or treating system the combination with solution-making vessels, and vessels for dividing and distributing the crude water of glass-like for freely expanding and maintaining the solution-making vessels at all times in a horizontal position, substantially as described.

2. In a water purifying or treating system, the combination with the vessels for dividing and distributing the crude water, and for making and delivering the treating agents, of glass-like supporting and maintaining the dividing and distributing vessels at all times in a horizontal position when their supports are subjected to movement, substantially as described.

3. In a water purifying or treating system, the combination with the vessels for dividing and distributing the crude water, and for making and delivering the treating solutions, of glass-like for freely expanding and maintaining these vessels in a horizontal position when their supports are subjected to movement, and flexible means to convey the water to and from the respective vessels or devices and to afford the necessary play to the same, substantially as described.

4. In a water purifying or treating system, the combination with the vessels for dividing and distributing the crude water, and for making and delivering the treating solutions, of glass-like for freely expanding and maintaining these vessels in a horizontal position when their supports are

subjected to movement, and a wide-mouthed hopper or funnel shaped receiving device adapted to receive and deliver the liquid from the distributing vessel to where required and to afford the necessary play thereto, substantially as described.

5. In a water purifying or treating system, the combination with a vessel for dividing and distributing the crude water, of glands for freely suspending and maintaining the same in a horizontal position when their support is subjected to movement, a stationary receiving vessel, and means for receiving and delivering the divided streams to the stationary vessel and adapted to afford the necessary play to the distributing vessel, substantially as described.

6. In an apparatus for the treatment or purification of water, the combination with a support subject to movement, of receiving vessels for the crude water and solution, rigidly secured to said support, solution-making vessels, distributing devices for receiving crude water and subdividing the same, glands for normally maintaining the distributing devices and solution-making vessels in a horizontal position, pipes connecting the distributing devices with the solution making and receiving vessels respectively, and pipes connecting the solution-making vessels with the receiving vessels, substantially as described.

7. In a feed-water purifying or treating system, the combination with a vessel for dividing and distributing the crude water, of means for freely suspending and maintaining the same in a horizontal position when subjected to movement, and a hopper or funnel-shaped receiver adapted to receive and deliver the divided streams to where required, and to afford the necessary play to the distributing vessel, said receiver being partitioned into compartments for the separate streams, substantially as described.

8. In a feed-water purifying or treating system, the combination with a bowl-shaped tank, a trough surrounding it divided into compartments, and a rotatable distributor for delivering the water to the several subdivisions of the tank, of delivery-pipes on the under part of the tank connected with the respective divisions of the tank, glands for freely suspending and maintaining the distributor in a horizontal position when subjected to movement, and means for receiving and delivering the divided streams to where required and adapted to afford the necessary play to the distributor, substantially as described.

9. In a feed-water purifying or treating system, the combination with the treatment-tank, of a vessel for dividing or distributing the crude water, solution-making apparatus, means for freely suspending and maintaining said distributing and solution-making apparatus in a horizontal position when subjected to movement, flexible pipes adapted to take a fraction of the water from the distributing to the solution-making apparatus, and from the latter to the treatment-tank, and means for receiving and delivering the larger remaining portion of the water from the distributing vessel to the treatment-tank, and adapted to afford the necessary play to said distributor, substantially as described.

10. In a feed-water purifying or treating system, the combination of treatment-tank Y having internal partition Y' making tubes I and tubes X, means for dividing or distributing the crude water, and for making and delivering the treating materials or solutions, glands H, I, K, P, adapted to support and maintain said vessels in a horizontal position when subjected to movement, receiver R, and flexible pipes K and T, substantially as described.

700,491. PROCESS OF MANUFACTURING FEAT HERRING.
HERZ HERRING, Washburn-Buckley, Germany. Filed Dec. 2, 1901. Serial No. 56380. (No specimens.)

Claim.—A process of manufacturing post supports for fuel, which consists in incorporating salt of lime and acid of tungsten with post while the latter is in its molten state, pressing and molding the compound into briquets, substantially as described.

700,492. METHOD OF MANUFACTURING FOR RAILWAY-CARS.
JAMES J. HANCOCK and FREDERICK H. HANCOCK, Milwaukee, Wis., assignors, by direct and mesne assignments, to the HANCOCK and WILLIAM H. HANCOCK, Chicago, Ill. Filed Mar. 13, 1902. Serial No. 57,380. (No model.)

Claim.—1. In a railway draft-rigging, the combination of the draft-bar or center sill, of side plates or stop-ends fitting between and secured thereto, a draw-bar having an extension or draft-iron in line therewith fitting between said side plates or stop-ends, a stationary friction-plate in line with the draw-bar in frictional sliding engagement with one of the horizontal sides of said draw-bar extension or draft-iron, double-leaf friction-plates on the opposite side of said draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction-plate, substantially as specified.

2. In a railway draft-rigging, the combination with the draft-bar or center sill, of side plates or stop-ends fitting between and secured thereto, a draw-bar having an extension or draft-iron in line therewith and fitting between said side plates or stop-ends, a stationary friction-plate in line with the draw-bar and in frictional sliding engagement with one of the sides of said draft-iron, a plurality of double-leaf friction-plates on the opposite side of the draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction-plate, substantially as specified.

3. In a railway draft-rigging, the combination with the draft-bar or center sill, of side plates or stop-ends fitting between and secured thereto, a draw-bar and a draft-iron in line therewith and fitting between said side plates or stop-ends, a stationary friction-plate in line with the draw-bar and in frictional sliding engagement with one of the sides of said draft-iron, a plurality of double-leaf friction-plates on the opposite side of the draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction-plate, substantially as specified.

4. In a railway draft-rigging, the combination of a draw-bar with a draft-iron in line therewith, a stationary friction surface or plate in line with the draw-bar and in frictional sliding engagement with one of the sides of the draft-iron, double-leaf friction-plates on the opposite side of the draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction surface or plate, substantially as specified.

5. In a railway draft-rigging, the combination with a draw-bar, of a draft-iron in line therewith, a stationary friction surface or plate in line with the draw-bar and in frictional sliding engagement with one of the sides of the draft-iron, a plurality of double-leaf friction-plates on the opposite side of the draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction surface or plate, substantially as specified.

6. In a railway draft-rigging, the combination with a draw-bar of a draft-iron in line therewith, a stationary friction surface or plate in line with the draw-bar and in frictional sliding engagement with one of the sides of the draft-iron, a plurality of double-leaf friction-plates on the opposite side of the draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction surface or plate, substantially as specified.

iron against said stationary friction surface or plate, the double-leaf friction-plates on the draft-iron being a snug fit and on the other a loose fit with the double-leaf friction-plates on the draft-iron so that one of the springs may be partially compressed before the other comes into action in both pulling and pushing, substantially as specified.

7. In a railway draft-rigging, the combination with a draw-bar, of a draft-iron in line therewith, a stationary friction surface or plate in line with the draw-bar and in frictional sliding engagement with one of the sides of said draft-iron, a plurality of double-leaf friction-plates on the opposite side of said draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction surface or plate, the double-leaf friction-plates of and for one of said blocks being of a less angle than the double-leaf friction-plates of and for the other friction-block, substantially as specified.

8. In a railway draft-rigging, the combination with a draw-bar, of a draft-iron in line therewith, a stationary friction surface or plate in line with the draw-bar and in frictional sliding engagement with one of the sides of said draft-iron, a plurality of double-leaf friction-plates on the opposite side of said draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction surface or plate, one of said friction-blocks coming into action after the spring of the other is partially compressed and the double-leaf friction-plates of the block coming last into action, being of a greater angle than those of the other friction-block, substantially as specified.

9. In a railway draft-rigging, the combination with a frame or casting fitting between and secured to the draft-bar and center sill of a car and having thereon a stationary friction surface or plate, of a draw-bar, a draft-iron in line with the draw-bar and having one of its sides in frictional sliding engagement with said friction surface or plate on said frame or casting and having on its opposite side double-leaf friction-plates, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing the draft-iron against said stationary friction surface or plate on the frame, said spring, friction-block, draft-iron and stationary friction surface or plate being all directly behind the draw-bar and in the line of draft, substantially as specified.

10. In a railway draft-rigging, the combination with a frame having thereon a horizontal friction surface or plate of a draw-bar, a draft-iron in line with the draw-bar and having its lower side in frictional sliding engagement with said stationary friction surface or plate on the frame and provided on its opposite side with a pair of double-leaf friction-plates, a pair of transversely-movable friction-blocks having corresponding double-leaf friction-plates and vertically-arranged springs acting against said friction-blocks and centrally pressing the draft-iron against said stationary friction surface or plate on the frame, said springs, friction-blocks, draft-iron and stationary friction surface or plate being all directly behind the draw-bar in the line of draft, substantially as specified.

11. In a railway draft-rigging, the combination with a draft-iron in line with the draw-bar and having a straight friction-plate on its lower side, and double-leaf friction-plates on its upper side, a stationary straight friction-plate supporting the draft-iron and in frictional sliding engagement therewith, a transversely-movable friction-block having double-leaf friction-plates in engagement with said friction-plate on the draft-iron, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction-plate, said draft-iron, friction-plate, friction-block and spring being all directly behind the draw-bar and in the line of draft and adapted to be mounted between the draft-bar and center sill of the car, substantially as specified.

12. In a railway draft-rigging, the combination of the draft-bar and center sill, of side plates or stop-ends fitting between and secured thereto, a draw-bar having an extension or draft-iron in line therewith fitting between said side plates or stop-ends, a stationary friction-plate in line with the draw-bar in frictional sliding engagement with one of the horizontal sides of said draw-bar extension or draft-iron, double-leaf friction-plates on the opposite side of said draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction-plate, said stationary friction-plate being removably secured to the side plate or stop-ends and having extension or projections at its ends engaging corresponding notches or projections on the stop-ends, substantially as specified.

13. In a railway draft-rigging, the combination of the draft-bar and center sill, of side plates or stop-ends fitting between and secured

thereto, a draw-bar having an extension or draft-iron in line therewith fitting between said side plates or stop-ends, a stationary friction-plate in line with the draw-bar in frictional sliding engagement with one of the horizontal sides of said draw-bar extension or draft-iron, double-leaf friction-plates on the opposite side of said draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction-plate, said side plates or stop-ends having guide-ways in which said friction-block reciprocates transversely to the draft-iron, substantially as specified.

14. In a railway draft-rigging, the combination with the draft-bar and center sill, of side plates or stop-ends fitting between and secured thereto, a draw-bar and a draft-iron in line therewith and fitting between said side plates or stop-ends, a stationary friction-plate in line with the draw-bar and in frictional sliding engagement with one of the sides of said draft-iron, a plurality of double-leaf friction-plates on the opposite side of the draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction-plate, said friction-blocks being independently movable and the side plates or stop-ends having a separate guide-way for each of said blocks, substantially as specified.

15. In a railway draft-rigging, the combination of a draw-bar with a draft-iron in line therewith, a stationary friction surface or plate in line with the draw-bar and in frictional sliding engagement with one of the sides of the draft-iron, double-leaf friction-plates on the opposite side of the draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction surface or plate, said stationary friction-plate being removably secured to the side plate or stop-ends and having shoulders or steps engaging corresponding shoulders or steps on the side plates or stop-ends, substantially as specified.

16. In a railway draft-rigging, the combination with a draw-bar, of a draft-iron in line therewith, a stationary friction surface or plate in line with the draw-bar and in frictional sliding engagement with one of the sides of the draft-iron, a plurality of double-leaf friction-plates on the opposite side of the draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction surface or plate, said friction-blocks each having a rectangular base fitting corresponding guide-ways in the side plates or stop-ends, substantially as specified.

17. In a railway draft-rigging, the combination with a draw-bar, of a draft-iron in line therewith, a stationary friction surface or plate in line with the draw-bar and in frictional sliding engagement with one of the sides of the draft-iron, a plurality of double-leaf friction-plates on the opposite side of the draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction surface or plate, said friction-blocks each having a rectangular base fitting corresponding guide-ways in the side plates or stop-ends, and provided with a dovetail slot to receive the spring, substantially as specified.

18. In a railway draft-rigging, the combination with a draw-bar, of a draft-iron in line therewith, a stationary friction surface or plate in line with the draw-bar and in frictional sliding engagement with one of the sides of the draft-iron, a plurality of double-leaf friction-plates on the opposite side of the draft-iron from said stationary friction-plate, a transversely-movable friction-block having corresponding double-leaf friction-plates, and a transversely-arranged spring acting against said friction-block and centrally pressing said draft-iron against said stationary friction surface or plate, said friction-blocks each having a rectangular base fitting corresponding guide-ways in the side plates or stop-ends and said stationary friction-plate being removably secured to the side plate or stop-ends, and having shoulders or steps engaging corresponding shoulders or steps on the side plates or stop-ends, substantially as specified.

700,493. MOTOR ENGINE. JAMES S. HANCOCK, Milwaukee, Wis., assignor of one-half to C. A. HANCOCK, Washburn, Iowa. Filed Nov. 20, 1901. Serial No. 54,661. (No model.)

Claim.—A rotary engine comprising a cylinder rigidly mounted; a

chance to said input-chamber and means of leading steam from past-chamber to said expansion-chamber substantially as specified.

700,424. PUMPS-ENGINE. EDWARD VAN BORN, New York, N. Y.
Filed Jan. 9, 1901. Serial No. 61,957. (No model.)

Claim.—1. In a sliding-valve, the combination with the handle and the spool, of a frictional connection between the handle and the spool, comprising a shaft having a loose gear mounted thereon and friction-disk carried by the shaft to engage each side of said gear, and means for interengaging the loose gear with the spool.

2. In a sliding-valve, the combination with the spool having a gear, of a shaft carrying friction-disk, a gear loose upon the shaft between the friction-disk, and means with the spool-gear, whereby both faces of the loose gear serve to locking contact.

3. In a sliding-valve, the combination with the spool and the handle, of a hollow shaft carrying friction-disk and a loose gear between the disk, means for axially adjusting one of said friction-disk, and means for interengaging the loose gear with said spool.

4. In a sliding-valve, the combination of a pivot having a tubular shaft mounted thereon, said shaft carrying a fixed friction-disk, a longitudinally-movable friction-disk and a loose gear between the friction-disk to be engaged thereby, a nut upon the hub of the movable disk to adjust the same, a handle on the shaft for rotating the same, a spool, and means for interengaging the loose gear with the spool.

700,425. CAR-TRUCK. HENRY E. KUTNER, Buffalo, N. Y.
Filed Nov. 27, 1901. Serial No. 61,957. (No model.)

Claim.—1. A side frame for diamond car-trucks having a lower arch-bar, and an upper arch-bar formed from a single piece of metal, and composed of a longitudinal top plate and vertical webs extending downwardly from the edges of said plate and provided at their lower edges with outwardly-extending flanges which are riveted to the end portions of the lower arch-bar, substantially as set forth.

2. A side frame for diamond car-trucks having a lower arch-bar, and an upper arch-bar formed from a single piece of metal, and composed of a longitudinal top plate and vertical webs extending downwardly from the edges of said plate and provided at their lower edges with outwardly-extending flanges which extend around the ends of the bar and which are riveted to the end portions of the lower arch-bar, substantially as set forth.

bar, substantially as set forth.

4. The combination with the side frame of a car-truck each having an upper arch-bar or compression member formed from a single piece of metal and composed of a longitudinal top plate and vertical webs extending downwardly from the edges of said plate and provided at their lower edges with outwardly-extending flanges, of a transverse member of a bottom plate, parallel webs extending upwardly from the edges of said plate and formed integral therewith and provided at their upper edges with outwardly-extending flanges, substantially as set forth.

5. The combination with the side frame of a car-truck each having an upper arch-bar or compression member formed from a single piece of metal and composed of a longitudinal top plate and vertical webs extending downwardly from the edges of said plate and provided at their lower edges with outwardly-extending flanges, of a transverse member of a bottom plate, parallel webs extending upwardly from the edges of said plate and formed integral therewith and provided at their upper edges with outwardly-extending flanges, said plates which are bolted or riveted to the flanges of the transverse webs and to the flanges of said upper arch-bar, substantially as set forth.

700,426. BICYCLE. IRVING W. KUTNER, Worcester, Mass.
Filed Oct. 14, 1901. Serial No. 61,957. (No model.)

Claim.—1. In a bicycle, the combination of a crank-shaft gear, a rear-wheel gear, an intermediate rim-gear connecting the crank-shaft gear and rear-wheel gear, and gears having their working faces grooved to receive a supporting-ring, which supporting-ring includes the intermediate gear, substantially as described.

2. In a bicycle, the combination of a grooved crank-shaft gear 10, a grooved rear-wheel gear 11, a supporting-ring 15 engaging said grooves, a rim-gear 20 journaled on a single set of bearing-balls 19 inside of the supporting-ring 15, and an open-centered casing 12 including said gear, substantially as described.

3. In a bicycle, the combination of a grooved crank-shaft gear 10, a grooved rear-wheel gear 11, a supporting-ring 15 engaging the grooves in said gears, a rim-gear 20 journaled on a single set of bearing-balls 19 inside of the supporting-ring 15, means for adjusting said supporting-ring 15 to take up wear, and an open-centered casing 12 including said gear, substantially as described.

Claim.—1. An improved bar comprising a tunnel having inlet and discharge openings, plate-carrying means within the tunnel, a flue beneath the tunnel-floor, a stack communicating with the tunnel and flue, and means for supplying heat to the tunnel and flue, substantially as shown and described.

2. An improved bar comprising a tunnel having inlet and discharge openings, plate-carrying means within the tunnel, a flue beneath the tunnel-floor, means adjacent the tunnel-inlet opening for supplying heat to the tunnel and flue, and a stack adjacent the tunnel-outlet opening having separate connections with the flue and tunnel, substantially as shown and described.

3. An improved bar comprising a circular tunnel having a transverse opening or interruption forming a discharging-space, the tunnel being provided with an inlet-opening and with heating means, an endless plate-carrier movable in the tunnel and traversing the said discharging-space, mechanism for actuating the conveyor, and means for closing the tunnel at opposite ends of the discharging-space with a portion of the conveyor in said space, substantially as shown and described.

4. An improved bar comprising a circular tunnel having a transverse opening or interruption forming a discharging-space, the tunnel being provided with an inlet-opening and with heating means, an endless series of plate-carriers movable in the tunnel, means for actuating the carrier, the length of the said tunnel-discharging space being the same as the length of any one of the carriers, and doors movable between the carriers for closing the tunnel at opposite ends of the discharging-space, substantially as shown and described.

5. An improved bar comprising a circular tunnel having a transverse opening or interruption forming a discharging-space, the tunnel being provided with an inlet-opening and with heating means, an endless series of plate-carriers movable in the tunnel, means for actuating the carrier, and means for closing the tunnel at opposite ends of the discharging-space with the discharging-carrier intermediate the closing means, substantially as shown and described.

6. An improved bar comprising a circular tunnel having an inlet-opening, an endless series of segmental-shaped plate-carriers movable in the tunnel, means for actuating the carrier, means for heating the tunnel, the tunnel being formed with a vertical opening or interruption corresponding in outline to any one of the carriers, and doors movable between the carriers for closing the tunnel at opposite ends of the said discharging-opening, substantially as shown and described.

7. An improved bar comprising a circular tunnel formed with an inlet-opening, an endless series of segmental-shaped carriers movable in the tunnel, means for actuating the carrier, the tunnel being formed with a transverse segmental-shaped opening or interruption corresponding in size to any one of the carriers, doors at opposite ends of said opening for closing the tunnel with a carrier positioned within said space for discharging, a horizontal flue beneath the tunnel-floor having its inlet and between the tunnel inlet and outlet openings, a stack adjacent the tunnel-outlet with which the tunnel and flue communicate, and means for supplying heat to the flue and tunnel, substantially as shown and described.

700,428. GLASS-DELIVERING APPARATUS. WASHINGTON B. KITE, Harrisville, Pa. Filed Sept. 4, 1901. Serial No. 74,265. (No model.)

2. The combination of a glass-furnace constructed with a plurality of ports, connected tracks leading to said ports, and a plurality of glass-removing devices movable on the tracks and common to all of said ports.

3. The combination of a glass-furnace constructed with a plurality of ports, a track leading from each of said ports, a single track operatively connected to each of said first-mentioned tracks, and a plurality of glass-removing devices common to all of said tracks and furnace-ports.

4. The combination of a glass-furnace constructed with a delivery-port and auxiliary ports, the latter being at opposite sides of the delivery-port, a plurality of ladling devices, ladle-conveying means, a main track-way for the latter extending from the delivery-port, and auxiliary ways extending from the main track-way to each of the auxiliary ports.

5. The combination of a furnace constructed with a delivery-port and an auxiliary port at each side of the delivery-port, a main overhead track extending from the delivery-port, a track extending from each of the auxiliary ports and communicating with the main track, trolley-carriages movable interchangeably over said tracks, and a ladling device carried by each carriage.

700,429. WRENCH. HENRY KITE and EDWARD J. LINDBERG, Harrisburg, Pa., assignors of one-third to Franklin P. Booth, Pittsburgh, Pa. Filed Sept. 20, 1901. Serial No. 77,912. (No model.)

Claim.—1. A wrench consisting of the shank, the rigid jaw on the shank, the sliding jaw on the shank, the vertical spring-pin connected to the sliding jaw and arranged in the shank, the stem or arm depending from the sliding jaw and provided with teeth, the guiding-strip, and the grasping-lever fulcrumed to the shank and having teeth on its upper end to engage the teeth on the depending shank.

2. In a wrench, the combination of the shank carrying the rigid jaw, the sliding jaw mounted on the said shank, the stem or arm depending from the sliding jaw having teeth on its inner face, the lever fulcrumed to the shank and having a grasping lower portion and teeth on the upper portion to engage the teeth of the said shank.

700,430. COMBINATION KEY AND READER. GEORGE A. LANE, LaGrange, Cal., assignor of one-half to Joseph F. Martin, LaGrange, Cal. Filed Sept. 20, 1901. Serial No. 77,129. (No model.)

Claim.—A drill consisting of a body portion having its lower end inclined to relation to the axis of said body, the rear portion of said end surface being plane to form an inclined flat heel, and the forward or toe portion of this same inclined lower surface of the drill having oppositely-

beveled surfaces forming a cutting edge, and tapered grooves upon the sides of said drill, said grooves being widest and deepest at the lower end of the drill, and said beveled lower surface extending from the edge of the long side of the drill to a point between and rearward of the center of the grooves, substantially as herein described.

700,481. FENCE-POST. CHARLES LEAM, Kingston, Ark. Filed Dec. 4, 1901. Serial No. 94,678. (No model.)

Claim.—1. In a fence the combination of a triangular post driven into the ground, having holes drilled through near its top in pairs on lines parallel to lines marking the altitude of the triangle from each side thereof, each pair of holes being drilled on a different plane from the other pairs of holes, bars formed integral with each edge of the post adapted to be clamped over the line-wires of the fence, and a board fastened to one edge of the post by means of wire nails passing through said board and holes drilled through the top of said post, substantially as shown and described.

2. In a fence, the combination of a post, triangular in cross-section, driven into the ground and having holes drilled through near its top in pairs on lines perpendicular to the opposite side of said post, each pair of holes being drilled on a different plane from the other pairs of holes, bars formed integral with each edge of the post to be alternately used to clamp the line-wires of the fence, said bars being closer together near the base of the post, and a board fastened to one edge of the post by means of wire nails passing through said board and said holes drilled near the top, said nails being clamped against said post, substantially as shown and described.

700,482. REVERSING MECHANISM. JAMES LAMONT, Quincy, Mass., assignor of one-half to Helen M. Fry, Boston, Mass. Filed Feb. 13, 1902. Serial No. 95,597. (No model.)

Claim.—1. In a reversing mechanism the combination of two bevel-gears, a clutch arranged between said gears for directly connecting the same, a support, one or more intermediate gears engaging said bevel-gears carried by said support, means for engaging and disengaging said clutch, and means for holding and releasing said support, substantially as described.

2. In a reversing mechanism the combination of a hollow shaft, a

bevel-gear secured thereto, a second bevel-gear, a clutch between said gears for directly connecting the same, a rod mounted in said shaft for operating the clutch, a support mounted to rotate with said gear, one or more intermediate gears engaging said bevel-gears carried by said support, and means for holding said support stationary, substantially as described.

3. In a reversing mechanism the combination of a hollow shaft, a second shaft, mechanism for driving one shaft from the other but in a reverse direction, clutch-shoes secured to the hollow shaft, a clutch-shoe surrounding said shaft and connected to said second shaft, a lever for operating said shaft, a rod mounted in said hollow shaft, and a cam for operating said lever carried by said rod, substantially as described.

4. In a reversing mechanism the combination of two bevel-gears, a cylindrical clutch-shoe secured to one gear, clutch-shoes secured to the other gear, a drum surrounding said gears, an intermediate gear engaging said gears carried by said drum, an adjustable cam within said clutch-shoes for operating the same, one of said clutches having an opening in line with said cam, and said above and drum having openings arranged to be brought into alignment with said cam, substantially as described.

5. In a reversing mechanism the combination of gears A¹, B¹, a clutch-shoe B² secured to gear B¹, a split sleeve A² secured to gear A¹, means for expanding the split sleeve A², a support D¹, intermediate gear C carried thereby, and means for holding said support stationary, substantially as described.

6. In a reversing mechanism the combination of disks A¹, B¹, gears A², B² secured thereto, clutch-shoes A³, B³, means for expanding sleeve A³, drum C, gear C, carried thereby, and means for holding drum C stationary, substantially as described.

7. In a reversing mechanism, the combination of gears A¹, B¹, a support C¹, intermediate gear C carried thereby, clutch-shoe B² and split sleeve A², a lever E¹ provided with legs B², the parts of sleeve A² having recesses between them in which the legs B² are located, a rod D¹, a cam D² on said rod for engaging the arm E of the lever E¹, substantially as described.

700,488. CONVEYER-CHAIN FOR MATCH-MACHINES. EDWARD H. LOWMEYER, Jr., Darby, Pa., assignor to Emma M. Thomas, Martin B. Brichman, and Harry K. Beck, Philadelphia, Pa., copartners trading as P. C. Thomas and Company, Philadelphia, Pa. Filed Mar. 4, 1902. Serial No. 94,678. (No model.)

Claim.—1. A conveyor for a match-machine consisting of lengthwise connecting-links, combined with a series of transverse composite bars secured to the links and each consisting of a bar of stamped sheet metal having a series of apertures, and a second bar of sheet metal bar-

ing a series of loops arranged through the apertures of the perforated bar to form supports for the match-sticks and in which the loops support the match-sticks on one side and the surfaces on the face of the perforated bar above and below the loops support the match-sticks on the other side.

2. A composite match-stick-supporting bar for a conveyor consisting of a sheet-metal bar having a bent flange for strength and its body formed with a series of apertures, combined with a second sheet-metal bar having a series of outwardly-projecting lapped portions passed through the apertures to form match-stick guides.

3. A composite match-stick-supporting bar for a conveyor consisting of a sheet-metal bar having a bent flange for strength and having its body formed with a series of apertures, combined with a second sheet-metal bar having a series of outwardly-projecting lapped portions passed through the apertures to form match-stick guides I and having their edges flaring outward as at I.

4. A composite match-stick-supporting bar for a conveyor consisting of a sheet-metal bar having a bent flange for strength and having its body formed with a series of apertures and grooves K above and below the apertures, combined with a second metal bar having a series of outwardly-projecting lapped portions extending through the apertures to form guides I in line with the grooves K for the match-sticks.

5. A composite match-stick-supporting bar for a conveyor consisting of a sheet-metal bar having a bent flange for strength and its body formed with a series of apertures the upper and lower edges of which flare backward as at K, combined with a second metal bar having a series of outwardly-projecting lapped portions extending through the apertures to form match-stick guides.

6. A composite match-stick-supporting bar consisting of a sheet-metal bar having a series of apertures and vertical guiding portions transversely to its length above and below said apertures, combined with a metal strip of less width than the bar and formed with a series of loops and attached to the sheet-metal bar and forming outwardly-projecting lapped portions over the apertures and in line with the guiding portions thereof, whereby the match-stick is properly held and guided.

7. A composite match-stick-supporting bar consisting of a bar having a series of perforations combined with metal lapped portions passed through the apertures to form a series of loops extending from the face of the bar for holding the match-sticks.

8. A composite match-stick-supporting bar consisting of a bar having a series of perforations and vertical guide-grooves in its body above and below the apertures transversely to the length of the bar combined with metal lapped portions passed through the apertures to form a series of loops extending from the face of the bar for holding the match-sticks and in line with the vertical guide-grooves.

9. A match-stick-supporting bar for a conveyor consisting of a sheet-metal bar the intermediate body of which is provided with perforations, combined with a second bar bent into a series of projecting portions I extending through the apertures and forming match-stick guide-apertures J bounded on one side by said projecting portions and on the other side by the body of the sheet-metal bar above and below the apertures.

10. In a conveyor for a match-machine, a section comprising the rack-bar B having legs C, combined with the composite supporting-bars for the matches each having flanges D¹ apertures I and slots d into which the rack-bar B and bar E having loops I extending through the apertures, and in which the flanges D¹ rest against the legs C of the rack-bar.

11. In a conveyor for a match-machine, a section comprising the rack-bar B having legs C, combined with the composite supporting-bars for the matches each having flanges D¹ apertures I and slots d into which the rack-bar B and bar E having loops I extending through the apertures, the flanges D¹ resting against the legs C of the rack-bar, and a spring G pressing against one of the composite supporting-bars and lapped over the legs C of the rack-bar for holding them in the slots d of the said supporting-bars.

700,484. REDUCING-VALVE. GEORGE W. LANE, Chicago, Ill. Filed Aug. 19, 1901. Serial No. 71,861. (No model.)

Claim.—1. In a reducing-valve the combination with the valve-casing and pressure-diaphragm arranged therein, of a slide-valve arranged to control the admission of liquid to the valve-casing, an operating member operatively connecting said slide-valve with the pressure-diaphragm and a toggle mechanism arranged to force the valve positively against its seat as it approaches its closed position.

2. In a reducing-valve the combination with the valve-casing and pressure-diaphragm arranged therein, of a slide-valve arranged to control the admission of liquid to the valve-casing, an operating member directly connecting the pressure-diaphragm with said slide-valve so that said parts move together positively, and an oscillatory member pivotally mounted within the valve-casing and operatively connected with said slide-valve

to move with the latter; the location of the pivotal axis of said oscillatory member and its operative connection with the slide-valve being arranged to force the slide-valve positively toward its seat as it approaches its closed position in its movement with the pressure-diaphragm.

3. In a reducing-valve, the combination with the valve-casing, of a pressure-diaphragm arranged to extend across the interior of the casing, an inlet-pipe opening into the casing through a valve-seat arranged in a plane substantially at right angles to the plane of the diaphragm, a slide-valve mounted in ways to reciprocate across said seat in a direction parallel with the direction of movement of the diaphragm in its vibration, an operating-stem operatively connected with the control portion of said diaphragm and directly engaging in its opposite end said slide-valve, a toggle member pivotally mounted at one end within the valve-casing and flexibly connected at its opposite end with the valve-operating mechanism, the pivotal axis of said toggle member being so located relatively to its point of connection with the valve-operating mechanism that said latter point moves through an arc which approaches the valve-seat as the valve is brought to its closed position, and a spring arranged to normally force said valve into opening position.

4. In a reducing-valve the combination of a valve-casing provided with a removable wall having the form of a cover-cap, a pressure-diaphragm arranged to extend across the interior of the casing at the point of juncture between the cover-cap and body of the casing, an inlet-pipe opening through a part of the side wall of the casing below the diaphragm and extending substantially at right angles thereto, a valve-seat block mounted upon the interior of the casing and provided with a port arranged in register with said inlet-pipe, ways formed in said valve-seat block, a slide-valve arranged to slide therein and provided upon its side remote from the valve-seat with a lug or projection, an operating-stem connected with the control portion of the diaphragm and having a recessed end portion operatively connected with the projection of the slide-valve, and a spring-bellows connected with said end and cap within which the upper end of said operating-stem is arranged to project, a coiled spring arranged within said barrel to act upon the operating-stem, means for adjusting the tension of said spring, and a toggle mechanism operatively connected with said slide-valve and casing to force the latter positively against its seat as it approaches its closed position, substantially as described.

5. In a reducing-valve the combination with the valve-casing provided with an inlet-pipe opening through one side thereof of a slide-valve arranged to reciprocate across said seat, and a toggle-lever pivotally mounted at one end within said casing at a point remote from, and substantially opposite said inlet-pipe and having its vibrating end operatively connected with said slide-valve by means of a dot-and-pin connection, whereby the valve is free to move away from its seat during its opening movement, but is forced positively to its seat as it approaches a closed position, and means for reciprocating said valve and pin, substantially as described.

6. In a reducing-valve the combination with the valve-casing provided with an inlet-pipe opening through one side thereof of a slide-valve arranged to reciprocate across said seat, and a toggle-lever pivotally mounted at one end within said casing at a point remote from, and substantially opposite said inlet-pipe and having its vibrating end operatively connected with said slide-valve by means of a dot-and-pin connection, whereby the valve is free to move away from its seat during its opening movement, but is forced positively to its seat as it approaches a closed position, and a spring arranged to act upon said toggle member to counterbalance the weight of the latter, and connected parts moving therewith, substantially as described.

700,485. RINGER. JAMES MADISON, Boston, Mass. Filed Aug. 11, 1901. Serial No. 71,861. (No model.)

Claim.—A hinge having flattened quills adapted to yieldingly engage with each other as described; a pin passing through said quills and having a button on each end; an inwardly-projecting shoulder upon each quill; two springs adapted to engage respectively with the said but-

tree and shoulders whereby the said hinges each become a right or left hand one, substantially as and for the purpose set forth.

700,486. DOOR-GUARD. DE WITT C. HENNER, Cincinnati, Ohio.
Filed Jan. 12, 1901. Serial No. 48,948. (No model.)

Claim.—1. In a safety gate or guard for hatchway-door, a gate or guard attached to a door at one end, and a hook having parallel sides adapted to engage with the other end of said guard, substantially as set forth.

2. In a safety gate or guard for hatchway-door, a brace hinged thereto, and a folding gate or guard pivoted at one end to said brace near its center, said gate being carried by the brace, substantially as set forth.

3. In a door-guard, a hinge attached to the door, a lay-tongue gate pivoted to said hinge by the end pivot of its central line, and means for engaging the free end of the gate when extended, substantially as specified.

4. In a door-guard, a hinge attached to a collar-door, a lay-tongue gate, the central and pivot of which is pivoted to said hinge, and a catch fixed to said collar-door adapted to engage the outer end of the gate when collapsed and folding inwardly against the door, substantially as specified.

5. In a door-guard, a hinge attached to a collar-door, a folding gate pivoted to the hinge, and means attached to the door adapted to engage the hinge and limit the lateral swing of the gate, substantially as specified.

6. In a door-guard, a hinge attached to the door, a folding gate pivoted to said hinge, a lay attached to the door adapted to be engaged by the lay-bar when the gate is folded in and released when the gate is extended, whereby the hinge stays in its bearings, and device attached to the door and hinge respectively adapted to interlock when the gate is swung to its central position and extended outwardly, substantially as specified.

7. A door-guard consisting of an extensible gate pivoted to a hinge which is in turn pivoted to a swinging door, and means connected to said hinge and door whereby the hinge is dropped automatically and locked against the hinge action, when the gate is extended, substantially as specified.

8. In a door-guard, a swinging door, a hinge attached thereto, a lay-tongue gate, the central joint of the first link-sections of said gate being pivoted to said hinge, means on the said door for engaging and retaining the free end of the gate when contracted and folded inward against the side of said door, and means on the opposite door for engaging and retaining the free end of the gate when extended across the aperture to be guarded, substantially as specified.

9. In a door-guard, a plate, a guard-hinge attached thereto, composed of oppositely-projected limbs, a folding gate pivoted between the limbs of said hinge, and interlocking device on said plate and hinge adapted to engage when the gate is swung to a predetermined position, substantially as specified.

700,487. APPARATUS FOR ELECTRICALLY OPERATING
TOOL. CHARLES R. HOOKER, Chicago, Ill., and CHARLES J. KELLY, Syracuse, Ind. Filed Apr. 11, 1900. Serial No. 12,494. (No model.)

Claim.—1. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids and to communicate a succession of blows to a tool, and independent and separated magnetic shields for said solenoids to concentrate the lines of force on the core, substantially as described.

2. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids and to communicate a succession of blows to a tool, said core being magnetically insulated from the solenoids, and independent and separated magnetic shields for said solenoids to reduce the air-gap and concentrate the lines of force on the core, substantially as described.

3. In an electrical apparatus for operating a tool, the combination

with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids, a non-magnetic sleeve between the core and each solenoid, and magnetic shields around the solenoids and insulated from each other, substantially as described.

4. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids, a magnetic shield surrounding each solenoid and a non-magnetic connection between the shields, substantially as described.

5. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids, a magnetic shield around each solenoid, and a non-magnetic cylinder forming a connection between the shields, substantially as described.

6. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, and electric circuits for alternately energizing the same, of removable contact connections in the circuit leading to one of the solenoids and arranged between said solenoids to engage terminals on the adjacent ends thereof for making permanent electrical connections between the two solenoids, substantially as described.

7. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids and electric circuits for alternately energizing the same, of removable contact connections in the circuit leading to one of the solenoids and consisting of spring-metal devices arranged between said solenoids and engaging terminals on the adjacent ends thereof for making permanent electrical connections between the two solenoids, substantially as described.

8. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core adapted to be operated by and through said solenoids, electric circuits for alternately energizing the solenoids, a non-magnetic mechanical connection between the solenoids and removable electric connections in the circuit leading to one solenoid and engaging the terminals thereof for making permanent electrical connections between the solenoids, substantially as described.

9. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core arranged to be reciprocated by and through said solenoids, a magnetic shield around each solenoid, a non-magnetic connection between the shields, electric circuits for alternately energizing said solenoids and electric connections in the circuit leading to one solenoid carried by the non-magnetic connection between the shields and consisting of spring contact-fingers engaging terminals on the adjacent ends of the solenoids, and adapted to be removed with the non-magnetic connection, substantially as described.

10. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids and a magnetic core adapted to be recip-

rocated thereby, of curved contacts on the adjacent ends of the solenoids, a non-magnetic connection between the solenoids and contact device carried by said non-magnetic connection and arranged to engage the curved contacts on the solenoids, substantially as described.

11. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids and provided with a hollow or recessed section and a circuit maker and breaker at said hollow or recessed section, substantially as described.

12. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids, said core being recessed or hollow at one end thereof, substantially as described.

13. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core adapted to be reciprocated by and through said solenoids, said core comprising a solid section and a hollow end section, and a circuit maker and breaker at said hollow end section, substantially as described.

14. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids, said core consisting of a solid section and a tubular section connected with said solid section, and a circuit maker and breaker at said tubular section, substantially as described.

15. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core arranged to be reciprocated by and through said solenoids, and having a recessed or hollow section, and a switch device operating in the hollow section of the core for switching the current alternately through the solenoids, substantially as described.

16. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core adapted to be reciprocated by and through said solenoids and having a recessed or hollow section, a movable contact carried by the hollow section of the core and stationary contacts arranged to be alternately engaged with said movable contact as the core is reciprocated for switching the current alternately through the solenoids, substantially as described.

17. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core adapted to be reciprocated by and through said solenoids, a tubular contact device carried by said core, and stationary contacts arranged within said tubular contact and adapted to engage therewith alternately as the core reciprocates to switch the current alternately through the solenoids, substantially as described.

18. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core adapted to be reciprocated by and through said solenoids, a tubular contact device carried by said core and partly insulated laterally, and stationary contact devices arranged within the tubular movable contact device and adapted to engage therewith to switch the current alternately through the solenoids, substantially as described.

19. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core adapted to be reciprocated by and through said solenoids, a tubular contact device carried by the core, and an adjustable stationary contact device arranged to engage with said movable tubular device, substantially as described.

20. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core adapted to be reciprocated by and through said solenoids, a tubular contact device carried by the core, a fixed stationary contact arranged to engage with the movable member and a stationary longitudinally-adjustable contact arranged to engage with the movable contact on the latter reciprocates and adapted to be adjusted to limit the reciprocating movement of the core, substantially as described.

21. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core adapted to be reciprocated by and through the solenoids, a tubular contact device partly insulated laterally and carried by the core, a fixed contact device arranged within the tubular movable contact to engage therewith, an adjustable stationary contact also arranged within the tubular movable contact, and means for holding the said adjustable contact from revolving with it as being adjusted longitudinally, substantially as described.

22. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core adapted to be reciprocated by and through said solenoids, a tubular movable contact device partly insulated laterally and carried by the core, a stationary contact 20 arranged to engage with the movable contact, a stationary contact 30 and a supporting-rod for said latter contact provided with a threaded end as

resists the contact, whereby said contact may be adjusted longitudinally by rotating the rod, substantially as described.

23. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids, of a magnetic core adapted to be reciprocated by and through said solenoids and having a recessed or hollow end section, a tubular contact device secured in the hollow end of the core and reciprocating therewith, and stationary contacts arranged within the tubular movable contact and adapted to engage therewith, substantially as described.

24. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids and having a recessed or hollow end section, a tubular contact device secured in the hollow end of the core and reciprocating therewith, a contact 20, a support for said contact, an insulated plate arranged within the tubular movable contact and above the support for the contact 20, a contact 30 resting upon said insulating-plate, a supporting-rod having a threaded end to receive the contact 30 and its other end projecting through the apparatus and adapted to be rotated to adjust the contact 30 on the end thereof longitudinally, substantially as described.

25. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids, a non-magnetic connection between the solenoids, a cap arranged at one end of the apparatus, and a tool-holder supported by said cap, substantially as described.

26. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids, a cap at one end of the apparatus, a sleeve secured in said cap and adapted to receive the core, and a tool-holder movably carried by the cap and adapted to be operated by the core, substantially as described.

27. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids, a hollow headpiece arranged at one end of the apparatus, and a circuit-clear device arranged in said hollow headpiece and adapted to be operated from the outside thereof to close the circuit and start the apparatus in operation, substantially as described.

28. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids, a hollow headpiece, contacts 54, 55 limited within said hollow headpiece, and a circuit-clear operating through the headpiece and adapted to engage said contacts, substantially as described.

29. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids, a hollow headpiece at one end of the apparatus, contacts 54, 55 arranged within said headpiece, a circuit-clear for engaging said contacts, curved contact devices 56, 57 and contact-fingers 58, 59, substantially as and for the purpose described.

30. In an electrical apparatus for operating a tool, the combination with a pair of aligned solenoids adapted to be alternately energized, of a magnetic core arranged to be reciprocated by and through said solenoids, a magnetic shield around each solenoid, a non-magnetic connection between the shielded solenoids, a cap connected to the outer end of one of said shields and a headpiece connected to the outer end of the other shield, substantially as described.

31. An electrical apparatus for operating a tool, comprising a pair of aligned solenoids adapted to be alternately energized, a magnetic core arranged to be reciprocated by said solenoids, a cylindrical magnetic shield insulating each solenoid, a cylindrical non-magnetic connection between the shields, a cap at the outer end of one shield, a hollow headpiece in the outer end of the other shield and a handle carried by said headpiece, substantially as described.

32. An electrical apparatus for operating a tool, comprising a pair of aligned solenoids adapted to be alternately energized, a magnetic core arranged to be reciprocated by said solenoids, a magnetic shield insulating each solenoid and concentrating the lines of force on the core, a non-magnetic connection between the solenoids, a hollow headpiece, contact device arranged within said headpiece and a switch device carried by the core, substantially as described.

33. An electrical apparatus for operating a tool, consisting of a body comprising a non-magnetic cylinder, a shielded solenoid connected to each end of said cylinder, a magnetic core, electric circuits for alternately energizing the solenoids to reciprocate the core, a hollow headpiece, a handle connected to said headpiece and a switch device carried by the core and operating in the hollow headpiece, substantially as described.

34. The combination with a core for operating a tool and means for

extending the core, of an insulating casing comprising a central cylinder having annular shoulders 14, 15 thereon, and cylinders 10, 11 arranged in the ends of the central cylinder and abutting against the shoulders thereon, substantially as described.

35. An electrical apparatus for operating a tool, consisting of a body comprising two solenoids each of which is provided with a magnetic shield including its ends and outer surface, a non-magnetic connection between said solenoids to maintain them in proper alignment, electrical circuits for alternately energizing said solenoids, and a magnetic core adapted to be reciprocated by the solenoids, substantially as described.

36. The combination with a core and means for reciprocating the same, of an insulating casing comprising a central cylinder, a cap, a hand-piece having a handle, and cylinders arranged between the central cylinder and cap and the hand-piece and central cylinder and all connected together, substantially as described.

700,488. BOTTLE-LABELLING MACHINE. FREDERICK HUBER, Worcester, Mass., assignor of one-half to John E. Hubert, Worcester, Mass. Filed Oct. 8, 1901. Serial No. 24,261. (No model.)

Claim.—1. In a labelling-machine, the combination of bottle-clamping mechanism, label gunning and picking-up fingers, and means for operating said fingers to move transversely with respect to the position of a bottle, to bring a label into place, and for withdrawing said fingers axially with respect to the bottle while the clamping mechanism acts to hold the label in place.

2. In a labelling-machine, the combination of the jaw forming the top member of the clamping mechanism, the sliding carrier carrying the lower member of the clamping mechanism, and wiping-rollers, the said lower member of the clamping mechanism being arranged to have a lost motion relatively to the carrier, and label-picking-up fingers mounted to turn on an axis and to slide axially of the bottle, substantially as described.

3. In a labelling-machine, the combination of the upper jaw of the clamping mechanism, a carrier carrying the lower jaw of the clamping mechanism, and wiping-rollers, a pivoted bracket, a sliding piece arranged on the pivoted bracket, and label-picking-up fingers carried by the sliding piece, substantially as described.

4. In a labelling-machine, the combination of the clamping mechanism, the pivoted bracket 34, the sliding piece 35 fitted thereon, the label-picking-up fingers 36 37 pivoted thereon, and the handle 38 for operating said fingers, substantially as described.

5. In a labelling-machine, the combination of the clamping mechanism, the wiping-rollers, the pivoted bracket 34, the sliding piece 35 fitted thereon, the label-picking-up fingers 36 37 pivoted to said sliding piece, the handle 38 for operating said fingers, and a spring 40 for holding said handle and fingers in normal position, substantially as described.

6. In a labelling-machine, the combination of the bottle-clamping mechanism, the wiping-rollers, the pivoted bracket 34, the sliding piece 35 thereon carrying the label-picking-up fingers 36 37, the locking de-

vise for locking the fingers in position relatively to the bottle, and connections so that the fingers will withdraw axially of the bottle, substantially as described.

7. In a labelling-machine, the combination of the bottle-clamping mechanism, the label-bar arranged at one side thereof, the label-carrying fingers, a pump-fountain, and connections so that the label-carrying fingers can be operated to take a label from the label-bar, bring the same in position relatively to the bottle, so that the clamping mechanism will then clamp the label intermediate of the fingers, and so that the fingers can then be withdrawn axially of the bottle, substantially as described.

8. In a labelling-machine, the combination of the clamping mechanism, the pivoted bracket 34, the piece 35 fitted to slide thereon, and carrying the label-picking-up fingers 36 37, a spring-pulled lever 54 for holding the label-fingers in their normal position, and a catch for engaging the lower end of said lever to lock said label-fingers in proper position relatively to the bottle, and to hold them so that they will withdraw axially of the bottle, substantially as described.

9. In a labelling-machine, the combination of the bottle-clamping mechanism, the pivoted bracket 34 carrying the sliding piece 35 having the label-picking-up fingers 36 37, the spring 46 for turning the bracket 34 to normal position, the spring-pressed bell-crank lever 54 for holding the label-fingers in their forward position, and the pivoted catch 56 arranged to lock the label-carrying fingers so that the same will withdraw axially of the bottle, substantially as described.

10. In a labelling-machine, the combination of the bottle-clamping mechanism, the pivoted bracket 34 carrying the sliding piece 35 having the label-picking-up fingers 36 37, the spring 46 for turning the bracket 34 to normal position, the spring-pressed bell-crank lever 54 for holding the label-fingers in their forward position, and the pivoted catch 56 having the extension 61 arranged to lock the label-carrying fingers in position relatively to the bottle, so that they will be constrained to withdraw axially thereof, the extension 61 preventing the forward movement of the sliding piece 35 until the fingers have swung to one side, substantially as described.

11. In a labelling-machine, the combination of the upper jaw of the clamping mechanism, the carrier carrying the lower jaw of the clamping mechanism, connections for raising and lowering the carrier, the pivoted bracket 34, the piece 35 fitted to slide thereon, and carrying the label-carrying fingers 36 37, a catch arranged to hold the label-fingers in proper position relatively to the bottle, and an extension 61 from the carrier arranged to withdraw the fingers axially of the bottle, substantially as described.

12. In a bottle-labelling machine, the combination of the upper jaw of the clamping mechanism, the sliding carrier carrying the lower jaw thereof, connections for raising and lowering the carrier, the spring-controlled pivoted bracket 34, the sliding piece 35 fitted thereon and carrying the label-carrying fingers 36 37, a spring-actuated bell-crank lever 54 for holding the sliding piece in its forward position, the pivoted catch 56 for engaging the lower end of the bell-crank lever and locking the label-carrying fingers in proper position relatively to the bottle, and an extension 61 for engaging the lower end of the bell-crank lever, lifting the same up to withdraw the label-carrying fingers axially of the bottle, and to lift the said bell-crank lever clear of the catch 56, whereby the bracket 34 and sliding piece 35 can turn to normal position, substantially as described.

13. In a bottle-labelling machine, the combination of the bottle-clamping mechanism, the label-carrying fingers 36 37 for bringing a label in proper position, and cams 39 39' on said label-carrying fingers for preventing the bottle from striking the label, substantially as described.

700,489. IRONING-MACHINE. JAMES J. O'BRIEN, St. Louis, Mo. Filed Oct. 7, 1901. Serial No. 77,706. (No model.)

Claim.—1. In an ironing-machine, the combination with an ironing-board, of a rotary iron adapted to cover the entire working face of said board, and means for moving said board and iron into contact.

2. In an ironing-machine, the combination with an ironing-board, of a rotary iron having its working face at right angles to its axis and adapted to cover the entire working face of said board, and means for moving said board and iron into contact.

3. In an ironing-machine, the combination with a standard, of an arm carried thereby, a shaft journaled in said arm, an oscillation-bearing having its movable part secured to said shaft, a sleeve attached to the movable part of said bearing, a rotary iron carried by said sleeve, and a filling of non-heat-conducting material in said sleeve.

4. In an ironing-machine, the combination with a standard, of an arm carried thereby, a shaft journaled in said arm, an oscillation-bearing having its movable part secured to said shaft, a sleeve carried by the movable part of said bearing, a rotary iron carried by said sleeve, a cap within said sleeve, and a filling of non-heat-conducting material within said cap.

5. In an ironing-machine, the combination with a rotary iron, of a bearing for said iron, a table cooperating with said iron, a burner for heating said iron, a perforated metal sleeve supporting said iron and protecting said bearing, and a filling of non-heat-conducting material in said sleeve.

6. In an ironing-machine, the combination with a rotary iron, of a movable table cooperating with said iron, a support for said table, and an extensible guard connecting said table and support.

7. In an ironing-machine, the combination with a standard, of an arm rigidly carried thereby, a rotating iron carried by said arm and having its working face at right angles to its axis, said iron being mounted to be immovable laterally, a second arm rigidly carried on said standard, a table mounted on said arm, said table being immovable laterally under the iron, and operating means for forcing said iron and table into contact.

700,440. NAIL-PULLER. WILLIAM FRANK, Flintville, Conn., assignor of two-thirds to William H. Woodruff and Norman A. Barnes, Flintville, Conn. Filed Aug. 21, 1901. Serial No. 73,573. (No model.)

Claim.—1. In a nail-puller, the combination with the rear and forward jaws thereof, the outer edge of the rear jaw being convex, of two plates rigidly secured by their forward ends to the opposite faces of the forward jaw and extending rearwardly beyond the outer edge of the rear jaw which is free to move between them, a pivot passing through the projecting rear ends of the plates, and a flange upon the said pivot and shaped to rest at its ends rather than between the same, its upper end being formed with a cam cooperating with the said convex outer edge of the rear jaw at a point above the greatest convexity thereof to force the said jaw downward under the nail, as well as toward the other jaw, and the lower end of the said flange constituting a fulcrum upon which the entire device turns as upon a center.

700,441. CAR-COUPLING. WILLIAM F. EDWARDS, Buffalo, N. Y., assignor to Gould Coupler Company, New York, N. Y., a Corporation of West Virginia. Filed Nov. 14, 1901. Serial No. 63,002. (No model.)

Claim.—1. The combination with the draw-head, and the knuckle, of a pivoted lock arranged lengthwise of the draw-head, a pivot-block to which said lock is pivoted, means for holding said block against displacement, and a spring carried by said block and acting rearwardly against the rear portion of said lock, substantially as set forth.

2. The combination with the draw-head, and the knuckle, of a pivoted lock arranged lengthwise of the draw-head, a pivot-block to which said lock is pivoted, means for holding said block against displacement, and a spring carried by said block and arranged in front of the rear end of the lock and acting to hold the front end of the lock in locking position, substantially as set forth.

3. The combination with the draw-head and the knuckle, of a pivoted lock arranged lengthwise of the draw-head, and a pivot-block to which said lock is pivoted and which has a recess extending thereto adjacent to said lock-pivot, means for holding said block against displacement, and a spring arranged in the recess in said block and acting against a part of said lock which is arranged adjacent to said recess, substantially as set forth.

4. The combination with the draw-head, and the knuckle, of a pivoted lock arranged lengthwise of the draw-head, a pivot-block to which said lock is pivoted and which has a recess extending thereto forwardly from its rear portion, means for holding said block against displacement, and a spring located in the recess in said block and acting against a part of said lock which is arranged opposite to said recess, substantially as set forth.

5. The combination with the draw-head, and the knuckle having a tailpiece provided with a lateral extension, of a horizontally-acting knuckle-lever for opening the knuckle, and a pivotal support for said knuckle-lever arranged adjacent to one side of the draw-head to form a shoulder in front of the lateral extension of the tailpiece when the knuckle is closed, substantially as set forth.

6. The combination with the draw-head, and the knuckle having a tailpiece provided with a lateral extension, of a horizontally-acting knuckle-lever for opening the knuckle, a pivot for the knuckle-lever, and a post for the said pivot adjacent to one side of the draw-head and arranged to form a shoulder in front of the lateral extension of the tailpiece when the knuckle is closed, substantially as set forth.

700,442. ADJUSTABLE FORMER-BLOCK FOR FORMING PAIR BOXES. BENJAMIN BARNES, Springfield, Mass. Filed Jan. 4, 1902. Serial No. 58,419. (No model.)

Claim.—1. An extensible and contractile former-block, consisting of the combination of the four blocks having red-sockets and yoke-receiving recesses in the line of the said sockets, with the adjusting-rods and yokes, substantially as described.

2. An extensible and contractile former-block, consisting of the combination of the four blocks having yoke-receiving recesses and red-sockets provided with the said wall 10 at the end, with the adjusting-rods arranged to bottom on the said wall 10, and yokes on the said rods for tightening the same, substantially as described.

3. The combination of the four blocks having red-sockets provided with the said wall 10 at the end, with the adjusting-rods internally threaded, the adjusting-rods fitted in the end of the said red and means for securing the said rods in their sockets, substantially as described.

700,448. CONCRETE-AND-METAL SKELETON FOR BUILDING PURPOSES. Otto Rupp, Bremen, Germany. Filed July 25, 1901. (No model.)

Claim.—1. The combination with a series of lengths of wire, of distribution-supports extending transversely to said wires, the said wires engaging two faces of said distribution-supports, the said distribution-supports adapted to be turned upon their longitudinal axis whereby the tension of the said wires may be adjusted, substantially as described.

2. In combination with a series of wires, of distribution-supports having two faces thereof engaged by said wires whereby the said supports may be turned on their longitudinal axis and the tension of the wires adjusted, substantially as described.

3. In combination with primary wires engaging two faces of the primary distributing-supports, of secondary distributing-supports engaged by the primary distributing-supports, secondary wires engaged by said secondary support whereby the tension of both is effected by the turning of the primary support upon its longitudinal axis, substantially as described.

4. In combination with a primary series of lengths of wire, of a secondary series of lengths of wire extending transversely to the said primary series, secondary distribution-supports engaging said secondary series, primary distribution-supports engaging said secondary supports and being engaged by said primary series of wires, whereby said primary supports may be turned on their longitudinal axis and adjustment of both series of wires effected, substantially as described.

700,444. RAD-IRON. CHARLES H. SHEPARD, New York, N. Y., assignor to Geo. H. Shepard, New York, N. Y. Filed July 19, 1901. Serial No. 68,977. (No model.)

Claim.—1. As a blast-iron, the combination, of the recessed body having a groove in its bottom, the interior channel around the upper edge of its walls and which is open at the top and rear end, the removable cover embodying the upper and lower plates having the air-space and the integrally-formed pillars between them, the integral burner embodying the inlet-channel, the vertical duct and the horizontal discharge-opening having the annular shoulder and annular groove for engaging a screen, and the asbestos packing between the body and cover, with the arched deflector having the central rib, the bottom openings and the front recesses, substantially as shown and described.

2. As a blast-iron, the combination, with the recessed body having a groove in its bottom, an interior channel around the upper edge of its walls and which is open at the top and rear end, the removable cover embodying the upper and lower plates having the air-space and the in-

tegrally-formed pillars between them, the integral burner embodying the inlet-channel, the vertical duct and the horizontal discharge-opening having the annular shoulder and annular groove, and a malleable and normally concave woven-wire disk within the said groove, and lying flat against the said shoulder; of an arched deflector having openings for discharge of flame on its bottom edges and recesses also for discharge of flame on its front edge and having a central rib for splitting the flame, substantially as shown and described.

3. As a blast-iron, the combination, of the recessed body having the interior channel around the upper edge of its walls and which is open at the top and rear end, and means for closing the rear opening, and the removable cover embodying the upper and lower plates having the air-space and the integrally-formed pillars between them, the integral burner embodying the inlet-channel, the vertical duct and the horizontal discharge-opening having the annular shoulder and the annular groove for engaging a screen, with the arched deflector having the central rib, the bottom openings and the front recesses, substantially as shown and described.

700,445. TYPE-WRITING MACHINE. CHARLES H. SHEPARD, Brooklyn, N. Y., assignor to Wyckoff, Macmaster & Beach, Inc., N. Y., a Corporation of New York. Filed Mar. 4, 1901. Serial No. 68,968. (No model.)

Claim.—1. In a ribbon-spool, the combination with a pair of flanges and a core, of a ball arranged between the spool-flanges and pivoted thereto, said ball having a cross-blade or ledge 9 provided with notches or openings, a recess in the core having an abrupt face opposed to said ledge, and impaling-needles projecting from said abrupt face opposite said notches or openings.

2. In a ribbon-spool, the combination with a pair of flanges and a core, of a clamp consisting of opposite arms 5 which are pivoted at their outer ends to the flanges, a cross-piece 6, and an extended finger 7 which curves around the core of the spool and is adapted to retain the clamp in working position.

3. In a ribbon-spool, the combination with a pair of flanges and a core, of a clamp consisting of opposite arms 5, which are pivoted at their outer ends to the flanges, a cross-piece 6, and an extended finger 7 which curves around the core of the spool and is adapted to retain the clamp in working position, said core having a recessed portion 8 formed in its periphery for engaging the tip of said finger.

4. In a ribbon-spool, the combination of a pair of flanges, a core, a ball comprising a cross-piece and arms 5 whose outer ends are pivoted to the flanges, a series of openings in said cross-piece, and a series of impaling-points fixed in the core opposite said openings.

5. In a ribbon-spool, the combination with a pair of flanges and a core, of a clamp arranged between the flanges and comprising a cross-piece and arms whose outer ends are pivoted to the flanges, said cross-piece having a portion 9 which is bent at an angle to the cross-piece in as in form a ledge, a row of notches or openings 10 formed in said ledge, a longitudinal recess formed in the spool-core, and a series of impaling-points fixed in said recess opposite said notches or openings.

6. In a ribbon-spool, the combination with a pair of flanges and a core, of a longitudinal recess formed in the core and having an abrupt face, and a clamp pivoted upon the spool-flanges and having a part which enters said recess and cooperates with said abrupt face to clamp the ribbon.

7. In a ribbon-spool, the combination with a pair of flanges and a core, of a ribbon-clamp comprising arms 5, cross-piece 6, ledge 9, and locking-finger 7, all formed from a single piece of sheet metal, and means upon the core for cooperating with said clamp to hold the ribbon.

8. In a ribbon-spool, the combination with a pair of flanges and a core, of a ribbon-clamp comprising arms 5, cross-piece 6, ledge 9 and locking-finger 7, all formed from a single piece of sheet metal, and means upon the core for cooperating with said clamp to hold the ribbon, one of said arms 5 having a finger-piece 14 which projects through an opening 15 in the longitudinal spool-flange.

9. In a ribbon-spool, the combination with a pair of flanges and a core, of a ball-like clamp whose opposite arms are pivoted at their outer ends to the inner sides of the flanges, means upon the core for cooperating with said clamp to hold the ribbon, said finger-piece upon one of the ball-arms which projects through a slot formed in the longitudinal spool-flange.

10. In a ribbon-spool, the combination of a core having a recess, an impaling-pin projecting into said recess, and a device for carrying the end of the ribbon into said recess and impaling it upon said pin.

11. In a ribbon-spool, the combination of a core having a recess, an impaling-pin projecting therethrough, and a swinging ball-like clamp adapted to carry the ribbon into said recess and from it upon said pin.

12. In a ribbon-spool, the combination of a core having a recess, a swinging clamp adapted to carry the end of the ribbon into said recess, and an impaling point or points for holding the ribbon in said recess.

13. In a ribbon-spool, the combination of a core having a recess, a swinging clamp adapted to carry the ribbon therethrough, an impaling point or points adapted to hold the ribbon in said recess, and means for holding the carrying portion of said clamp within said recess.

14. In a ribbon-spool, the combination of a core having a recess, a swinging clamp adapted to carry the ribbon therethrough, an impaling point or points adapted to hold the ribbon in said recess, and means on said clamp for embracing said core and holding said clamp in working position.

700,446. PRESERVING COMPOUND. RAYMOND C. SHAW, Portland, Me. Filed Feb. 26, 1902. Serial No. 68,967. (No specimens.)
Claim.—A preserving compound consisting of sulfur, magnesia, charcoal, melasse, chalk and zinc, substantially as described.

700,447. PICTURE-PROJECTING APPARATUS. GEORGE W. SMITH, Evanston, Ill. Filed June 20, 1900. Serial No. 68,967. (No model.)

Claim.—1. An optical projecting apparatus, embracing an incandescent, a slide-holder therein, said incandescent being provided with a space or passage outside of the slide-holder to permit the passage of the light around the same, a condensing-lens in said passage or space, an object-lens, a source of light, and reflectors located both in advance and at the rear of the plane of said slide-holder, whereby light from said source of light may be thrown on both sides of a picture in said slide-holder.

2. An optical projecting apparatus, comprising an incandescent, a slide-holder therein, said incandescent being provided with a space or passage outside of the slide-holder, to permit the passage of the light around the same, a condensing-lens in said passage or space, an object-lens, a source of light, and reflectors located both in advance and at the rear of the plane of said slide-holder including one or more obliquely-arranged reflectors adapted to change the course of the rays of light, whereby light from said source of light may be thrown on both sides of a picture held in said holder.

3. An optical projecting apparatus, comprising an incandescent, a slide-holder therein, said incandescent being provided with a space or passage outside of the slide-holder, to permit the passage of the light around the same, a condensing-lens in said passage or space, an object-lens, a source of light, reflectors located at the rear and in front of the plane of the slide-holder including one or more reflectors arranged obliquely to change the direction of the rays of light and a condensing lens or lenses interposed between the source of light and the said slide-holder.

4. An optical projecting apparatus comprising a slide-holder, an objective lens, a source of light located at one side of and in front of the slide-holder, a reflector to throw light upon the front face of an opaque picture in the slide-holder and the other at the rear of the slide-holder, said latter reflector operating to throw light through a transparent picture in the said slide-holder.

5. An optical projecting apparatus comprising a slide-holder, an objective lens, a source of light located in front of and at one side of the slide-holder, a reflector located in position to throw light upon the front face of an opaque picture in the slide-holder, two condensing-lenses one

at the rear of the source of light and the other at the rear of the slide-holder and two oblique reflectors located at the rear of said condensing-lenses, said oblique reflectors being constructed to throw light through a transparent picture in said slide-holder.

700,448. ADDRESS DEVICE. MORRIS A. SMITH, Cedar Rapids, Iowa. Filed Jan. 2, 1902. Serial No. 68,968. (No model.)

Claim.—1. In an adding device of the class described, the casing, a graduated register-disk working within and outside of the casing, a reciprocating plunger carrying an actuating member cooperating with the disk to impart thereto a step-by-step movement, and a single resting device arranged to yieldingly hold the actuating member in engagement with the disk and also to yieldingly thrust the plunger in the direction of its reciprocation.

2. In an adding device of the class described, the casing, a graduated register-disk rotatably mounted within the casing and constituting a register-disk, a reciprocating plunger having an exposed pressure-point and carrying at its inner end an actuating-dog rigid therewith and having a side point engaging the register-teeth of the disk, means for yieldingly maintaining the dog in engagement with the register-teeth, and a release-button also rigidly connected with the plunger and projecting to a point anterior of the casing.

3. In an adding device of the class described, the casing, a graduated register-disk working within and outside of the casing and provided with register-teeth, a reciprocating plunger having an exposed pressure-point and carrying at its inner end an actuating-dog whose point engages the register-teeth of the disk, and a single resting-spring cooperating with the plunger and dog, and arranged at an angle to provide for yieldingly pressing the dog in a lateral direction and also for thrusting the plunger in a longitudinal direction.

4. In an adding device of the class described, a casing having a longitudinal guideway, a dot, and an end opening, a guide-tube projecting beyond one end of the casing, a graduated register-disk working within the said guideway and through the end opening of the casing, said disk having register-teeth, a plunger-stem extending through the casing and guide-tube and provided with an exposed pressure-point, said plunger-stem also carrying at its inner end a dog whose point cooperates with the register-teeth of the disk, a single resting-spring cooperating with the plunger-stem and its dog, and a release-button rigidly connected with the plunger and having its shank arranged to work within the dot in the casing.

5. In an adding device of the class described, the combination of the casing having at one side thereof a longitudinal guideway, a graduated register-disk mounted within the casing and fitting the guideway thereof, means for actuating said disk, and a coiled friction-spring seated within the register-disk upon the side opposite the guideway and having one end entering a pressure against the adjacent wall of the casing.

700,449. FINE-WATER REGULATOR. CHRISTOPHER H. BRUNNEN, Windsor, Conn. Filed July 1, 1901. Serial No. 68,969. (No model.)

Claim.—A feed-water system consisting of a vertically-arranged tubular shell, a feed-water pipe with one end closed and an opening through its side, extending vertically into the shell, a float with a control opening, the walls of which opening fit the exterior of the feed-water pipe, that is adapted to move up and down the feed-water pipe so that the walls of its control opening will close and open the opening through the side of the feed-water pipe, a pump connected with the feed-water pipe, a con-

section from the feed-water pipe to a supply-tank each side of the pump, a check-valve in the feed-water pipe each side of the pump, and an adjustable relief-valve located in the connection from the feed-water pipe to the supply-tank that is between the pump and the feed-valve shell, substantially as specified.

700,450. VEHICLE RUNNING-GEAR. GEORGE W. H. GUNN, Windsor, Conn. Filed Aug. 31, 1901. Serial No. 74,088. (No model.)

Claim.—1. A running-gear consisting of a rear axle, a fixed front axle, a spring located above and supported by the front axle, reaches extending forwardly from the rear axle and terminating near the front axle, a yoke connecting the front ends of the reaches and supported by the spring on the front axle, and flexible braces extending from the reaches to the outer ends of the front axle, substantially as specified.

2. A running-gear consisting of a rear axle, a fixed front axle, a spring located above and supported by the front axle, reaches extending forwardly from the rear axle and terminating near the front axle, a yoke connecting the front ends of the reaches, and supported by the spring on the front axle, and flexible braces extending from the reaches to the outer ends of the front axle, substantially as specified.

3. A running-gear consisting of a rear axle, a fixed front axle, a spring located above and supported by the front axle, reaches extending forwardly from the rear axle and terminating near the front axle, an upwardly-extending yoke connecting the front ends of the reaches, and supported by the spring on the front axle, and flexible braces extending from the reaches to the outer ends of the front axle, substantially as specified.

4. A running-gear consisting of a rear axle, a fixed front axle, a spring located above and supported by the front axle, reaches extending forwardly from the rear axle and terminating near the front axle, an upwardly-extending yoke connecting the front ends of the reaches, a pivotal connection between the yoke and the spring on the front axle, and flexible braces connecting the reaches with the outer ends of the front axle, substantially as specified.

5. A running-gear consisting of a rear axle, a fixed front axle, a spring located above and supported by the front axle, reaches extending forwardly from the rear axle and terminating near the front axle, an upwardly-extending yoke connecting the front ends of the reaches, a pivotal connection between the yoke and the spring on the front axle, and flat bars that yield vertically but not horizontally, connecting the reaches with the outer ends of the front axle, substantially as specified.

6. A vehicle having a rear axle, a fixed front axle, side springs mounted on the rear axle, a cross-spring located above and supported by the

front axle, reaches extending forwardly from the rear axle and terminating near the front axle, an upwardly-extending yoke connecting the front ends of the reaches, a pivotal connection between the yoke and the cross-spring, flexible bars connecting the reaches with the outer ends of the front axle, and a body supported at the front end by the cross-spring and at the rear end by the side springs, substantially as specified.

700,451. MATCH-SAFE. GEORGE E. STATER, Portsmouth, Ohio. Filed Dec. 10, 1901. Serial No. 58,418. (No model.)

Claim.—1. A match-safe comprising an elongated plate having a match-slot in its lower portion, a match-tray holder secured to the under side of the plate adjacent to the match-slot, means formed integral with the tray-holder for preventing the withdrawal of the match-tray, and a bracket secured to the plate adjacent to its upper end for supporting the said plate in an inclined position.

2. A match-safe comprising an elongated plate having a transverse match-slot opening into a finger-aperture formed in its lower portion, a tray-holder secured to the under side of the plate adjacent to the match-slot to receive and retain the lower end of a match-tray, and a supporting-stand secured to the plate, having formed in its upper portion means for supporting the upper end of the match-tray.

3. A match-safe comprising an elongated plate having a match-slot formed in its lower portion, a tray-holder secured to the under side of the plate adjacent to the match-slot, a bracket secured to the said plate adjacent to its upper end, a bracket having shoulders in alignment with the bottom of the tray-holder and adapted to support the upper end of the match-tray.

4. A match-safe comprising a plate having a transverse match-slot opening into a finger-aperture formed in its lower portion, a match-tray holder having prongs formed integral therewith adapted to be inserted into the plate to secure the holder in position, and a bracket for holding the safe in an inclined position.

5. A match-safe comprising a plate having a transverse slot opening into a finger-aperture formed in its lower portion, a tray-holder secured to the under side of the plate adjacent to the match-slot, means to prevent the withdrawal of the match-tray and a bracket for supporting the match-tray secured to the plate adjacent to its upper end and having its upper end provided with a support for the upper end of the said match-tray.

6. A match-safe comprising a plate having a match-slot formed in its lower portion, a match-tray holder formed with prongs adapted to be inserted into the plate to secure the holder in position, an integral prong on the upper edge of the tray-holder for preventing the withdrawal of the tray and means for holding the safe in position.

700,452. BEEHIVE CATCHER. RUDOLF SCHMIDT, Berlin, Germany. Filed July 10, 1901. Serial No. 68,048. (No model.)

Claim.—1. A bee-hive catcher comprising a lower trap-compartment communicating with the hive and provided with an exit-opening in line with such communication, a trap-board pivoted intermediate its ends in said compartment, and means for causing said trap-board to pivot in position to permit, or to prevent, respectively, the passage of the bees through said exit, substantially as described.

2. A bee-hive catcher comprising a lower trap-compartment communicating with the hive and provided with an exit-opening in line with such communication, a trap-board pivoted intermediate its ends in said compartment, a hinged side to said compartment having a vertical slot, and a spring-latch in said slot whereby the trap-board may be held in position to permit or prevent the passage of the bees through said exit, substantially as described.

3. A bee-hive catcher comprising a lower compartment, an intermediate queen and drone compartment, and an upper compartment, the

lower compartment communicating with the hive and with the intermediate compartment by openings to permit the passage of the whole swarm and the intermediate and upper compartments communicating by means of openings to permit of the workers only, the lower compartment having an exit-opening in line with its communication with the hive, a trap-board pivoted in the lower compartment, and means whereby said trap-board may be set and held in position to permit, or prevent, the passage of the swarm through said exit, substantially as described.

700,453. RULE, BOOK-HOLDER, AND MARKER COMBINED. THOMAS D. THOMAS, Hoboken, Iowa. Filed Jan. 31, 1902. Serial No. 81,308. (No model.)

Claim.—A book-holder comprising a straight rigid bar having perforations in its ends and on elastic cord or tape having hooks at its ends as shown and described for the purposes stated.

700,454. SECONDARY ELECTRIC CIRC. SAMUEL P. THOMAS, New Haven, Conn. Filed Feb. 25, 1901. Serial No. 68,298. (No model.)

Claim.—1. In a device of the character described, a drum, a plurality of projections on said drum, a movable frame, a locking-arm carried by said frame adapted to engage one of said projections, a propelling-arm carried by said frame adapted to rotate said drum by the same movement which releases said locking-arm, an electromagnet for moving said frame, and an electric circuit for controlling said magnet, and means for making and breaking said circuit through one of said projections.

2. In combination, a drum, an electric circuit, a circuit-closer, an electromagnet in said circuit, means to normally lock said drum from rotation, means to first put said drum under a relative tension while said drum is locked and then release said drum and allow the same to rotate, means to stop the rotation of said drum after a certain amount of rotation, and means to control said electric circuit.

3. In combination, a drum, a plurality of projections thereon, a pivoted frame, a locking-arm carried by said frame and normally engaging one of said projections, a propelling-arm carried by said frame arranged to coast with said projections to move said drum, an electromagnet for moving said frame, an electric circuit for controlling said electromagnet and means for opening and closing said circuit.

4. In combination, a drum, a plurality of projections at the rim of

said drum, a pivoted frame, a locking-arm rigidly mounted on said frame and normally engaging one of said projections, a flexible propelling-arm mounted on said frame adapted to press against said drum, and means to operate said frame.

5. In combination, a drum, a plurality of projections thereon, a pivoted frame, a locking-arm rigidly mounted on said frame and normally engaging one of said projections, a flexible propelling-arm rigidly mounted on said frame adapted to coast with said projections to rotate said drum, and means to operate said frame.

6. In a device of the character described, a drum, a plurality of projections on said drum, a movable frame, a locking-arm carried by said frame adapted to engage one of said projections, a flexible propelling-arm carried by said frame adapted to rotate said drum by the same movement which releases said locking-arm, and means for operating said frame.

7. In combination, a drum, a plurality of projections thereon, a pivoted frame, a locking-arm rigidly mounted on said frame and normally engaging one of said projections, a flexible propelling-arm mounted on said frame adapted to coast with said projections to rotate said drum, and an electromagnet for operating said frame.

8. In combination, a drum, a plurality of independent projections at the rim of said drum one of said projections being an electric conductor insulated, another projection being insulated, a normally open electric circuit, one terminal of which is said insulated projection, another terminal of said circuit comprising a circuit-closing blade which lies in the path of movement of said projections on said drum, an electromagnet in said circuit and means operated by said electromagnet to rotate said drum.

9. In combination, a drum, a plurality of projections carried by the frame of said drum one of said projections being an electric conductor insulated, another projection being insulated, a normally open electric circuit one terminal of which is said insulated projection, another terminal of said circuit comprising a flexible circuit-closing blade which lies in the path of movement of said projections on said drum, an electromagnet in said circuit and means operated by said electromagnet to rotate said drum.

10. In combination, a drum, a plurality of projections thereon, means to normally lock said drum from rotation, means to bear against and move said projections, both of said means being rigidly secured together and having a common pivot, an electromagnet to move said means, and an electric circuit for energizing said magnet and means for making and breaking said circuit through said projections.

11. In combination, a drum, a plurality of projections thereon, means to normally lock said drum from rotation, means to bear against and move said projections, both of said means having a common pivot, an electromagnet to move said means, and an electric circuit for energizing said magnet and means passing through at least one of said projections.

12. In combination, a drum, a plurality of projections thereon, a spring-pressed pivoted frame, a locking-arm rigidly mounted on said frame and normally engaging one of said projections, a flexible propelling-arm rigidly mounted on said frame adapted to coast with said projections to rotate said drum, and means to operate said frame.

700,455. STAIRWAY. GEORGE C. TILTON, Quincy Island, N. Y. Filed Sept. 28, 1901. Serial No. 78,484. (No model.)

Claim.—1. In a stairway, the combination with a reciprocating stair-section, guides or ways therefor, means whereby it is reciprocated and a stair-lading, of a child in constant communication between said stair-section and said lading, substantially as described.

2. In a stairway, the combination with a reciprocating stair-section, guides or ways therefor, means whereby it is reciprocated and a stair-lading, of a child hinged to said section and maintained in constant contact with said lading, substantially as described.

3. In a stairway, the combination with a reciprocating stair-section, guides or ways therefor, means whereby it is reciprocated and top and bottom stair-ladings, of a child hinged to the top end of said stair-section and maintained in constant contact with said top lading and a swinging child carried by the lowermost end of said stair-section and moving in a slot in said bottom lading, substantially as described.

4. In a stairway, the combination with a reciprocating stair-section, guides or ways therefor, means whereby it is reciprocated and a top and a bottom stair-lading, of a hand-carried by and reciprocating with

raid stair-section and shields in constant communication between the top and the bottom of said stair-section and the top and the bottom landing respectively, substantially as described.

700,456. CLOCK STRIKING MECHANISM. ARTHUR TOMPKINS, JR. Louis, Mo. Filed Nov. 5, 1900. Serial No. 38,646. (No model.)

Claim.—1. In a striking mechanism for clocks, a gang for sounding the hours, a gang for sounding quarter-hours, a meter, operating connections between said meter and gangs, an hour-controlling mechanism, a separate and independently-movable quarter-hour-controlling mechanism, means for actuating both said controlling mechanisms during each quarter-hour, and means actuated by the movement of one of said controlling mechanisms for shifting said operating connections from one gang to the other.

2. In a striking mechanism for clocks, a gang for sounding the hours, a gang for sounding quarter-hours, a controlling device for each of said gangs, a quarter-hour small-wheel for one of said controlling devices, an hour small-wheel for the other of said controlling devices, said small-wheels being independently pivoted on a common axis, and an actuating device provided with three arms for actuating said quarter-hour small-wheel and one arm for actuating both small-wheels.

3. In a striking mechanism for clocks, a gang for sounding the hours, a gang for sounding fractions of hours, a meter, operating connections between said meter and gangs, a pair of controlling-racks for said gangs, a pair of independently-movable detents for said racks, means for simultaneously disengaging said detents from said racks, means for independently returning said racks, and means for automatically shifting said operating connections from one gang to the other after the return of the first rack.

4. In a striking mechanism for clocks, a gang for sounding the hours, a gang for sounding fractions of hours, a meter, operating connections between said meter and gangs, a pair of controlling-racks for said gangs, a pair of independently-movable detents for said racks, a pin carried by one of said detents and extending beneath the other, means for moving said pin and thereby simultaneously disengaging said detents from said racks, means for independently returning said racks, and means for automatically shifting said operating connections from one of said gangs to the other after the return of the first rack.

5. In a striking mechanism for clocks, a gang for sounding hours, a gang for sounding quarter-hours, a meter, operating connections between said meter and gangs, a pair of controlling-racks for said gangs, a pair of independently-movable detents for said racks, means for simultaneously disengaging said detents from said racks, means for independently returning said racks, and means actuated by the return of the first of said racks for shifting said operating connections from one of said gangs to the other.

700,457. SHAFI-COUPLES. ARTHUR E. TOWNE, JR. Boston, Pa. Filed Feb. 10, 1902. Serial No. 15,000. (No model.)

Claim.—1. A coupling for shafts, rods and the like, comprising a notional sleeve tapering from a middle point toward its extremities and having longitudinal grooves in its outer side, series of rings or bands fitted upon the tapering and portions of the sleeve, and lugs seated in the said grooves and having their ends portions upset, substantially as set forth.

2. The herein-described coupling for shafts, rods and the like com-

prising a notional sleeve tapering upon its outer side from a middle point toward its extremities and having longitudinal grooves, series of rings or bands for each end portion of the sleeve and having their openings of varying size and tapering to conform to the taper of the sleeve, and lugs fitted in the said grooves and having their ends ends upset, substantially as specified.

700,458. SAFETY APPLIANCE FOR ELEVATORS. SHARMA R. TRAFF. New York, N. Y. Filed Oct. 19, 1901. Serial No. 78,708. (No model.)

Claim.—1. The car, the cushioning-cylinder thereon having elastic gaskets and having the projecting piston-rod, and means for relieving the pressure in said cylinder when said fluid is compressed thereby by the piston, combined with steps normally out of the path of said piston-rod, and means operable from the car for effecting the movement of said steps into the path of said piston-rod for arresting the car; substantially as set forth.

2. The car, and the cushioning-cylinder thereon containing elastic gaskets and having the projecting piston-rod, combined with the series of steps normally out of the path of said piston-rod, lever mechanism for controlling said steps, and an arm connected with the car and adapted, when moved from its normal position, to engage said lever mechanism for effecting the movement of the proper step into the path of said piston-rod, for receiving said rod and arresting the car; substantially as set forth.

3. The car, and the cushioning-cylinder thereon mounted at opposite points thereon and having the downwardly-projecting piston-rod, said cylinder containing elastic gaskets and having the steps disposed along the elevator-shaft and normally out of the path of said rod, and means operable from the car for moving said steps into the path of said piston-rod for arresting the car; substantially as set forth.

4. The car, and the cushioning-cylinder thereon mounted at opposite points thereon and having the downwardly-projecting piston-rod, combined with the series of steps disposed at opposite points along the elevator-shaft and normally out of the path of said rod, lever mechanism also arranged at opposite points along the elevator-shaft for controlling said steps, and arms connected with the car and adapted when moved from their normal position to engage said lever mechanism for effecting the movement of the

proper steps into the path of said piston-rod for receiving said rod and arresting the car; substantially as set forth.

5. The car, the cushioning-cylinder thereon mounted at opposite points thereon and having the downwardly-projecting piston-rod, and the pipe 60 connecting said cylinders and affording free communication from one cylinder to the other, combined with steps disposed along the elevator-shaft and normally out of the path of said rod, and means operable from the car for moving said steps into the path of said piston-rod for arresting the car; substantially as set forth.

6. The car, the cushioning-cylinder thereon and having the downwardly-projecting piston-rod, the reservoir for compressed air, and means for automatically charging said cylinder from said reservoir upon the ascent of the car, combined with a step adapted when in the proper position to receive the end of said piston-rod and effect the stoppage of said car; substantially as set forth.

7. The car, the cushioning-cylinder thereon having the downwardly-projecting piston-rod, the reservoir for compressed air, the valve 41 leading to said cylinder and having the valve 42 and valve-stem 43, the pipe leading to said cylinder and the funnel 46 on said pipe and adapted on the ascent of the car to pass over the end of said valve and unseat said valve for enabling the automatic charging of said cylinder from said reservoir, combined with a step adapted when in the proper position to receive the end of said piston-rod and effect the stoppage of said car; substantially as set forth.

8. The car, the cylinder thereon containing air and having the projecting piston-rod, and the valve 43 within reach of the attendant in the car for establishing communication between the interior of said cylinder and the atmosphere, combined with a step adapted when in the proper position to receive the end of said piston-rod and effect the stoppage of said car; substantially as set forth.

9. The car, the cylinder thereon having the downwardly-projecting piston-rod, the reservoir for compressed air, means for charging said cylinder from said reservoir, the pump for charging said reservoir, and means connected with the car-holding device for actuating said pump, combined with a step adapted when in the proper position to receive the end of said piston-rod and effect the stoppage of said car; substantially as set forth.

10. The car, and the cushioning-cylinder thereon having the downwardly-projecting piston-rod, combined with the several steps 79 along the line of the elevator-shaft, the hinged beam 90 containing said steps, the sliding beam 100 loosely connected with said steps, means for normally holding said steps out of the path of said piston-rod, and means operable from the car for moving one of said steps into the path of said piston-rod for arresting the car; substantially as set forth.

11. The car, the cushioning-cylinder thereon having the downwardly-projecting piston-rod, the vertical beam 80 along the elevator-shaft, and the transverse beam 81 in said shaft, combined with the several steps 79 along said shaft, the hinged beam 90 containing said steps and supported by said beam 80, the hinged beam 100 connected with said steps and passing around said beam 80 above and adapted to rest on said beam 81, and means operable from the car for moving one of said steps into the path of said piston-rod for arresting the car; substantially as set forth.

12. The car, and the cushioning-cylinder thereon having the downwardly-projecting piston-rod, combined with the step 79 at the side of the elevator-shaft and normally out of the path of said piston-rod, the lever 96 having the arm 102 to hold the said step out of the path of said piston-rod and an arm 97 to move said step into the path of said piston-rod, and means operable from the car for actuating said lever 96; substantially as set forth.

13. The car, and the cushioning-cylinder thereon having the downwardly-projecting piston-rod, combined with the step 79 at the side of the elevator-shaft and normally out of the path of said piston-rod, the lever 96 having the arm 102 to hold the said step out of the path of said piston-rod and an arm 97 to move said step into the path of said piston-rod, the transverse rod 95 connected at one end with said lever 96, the bell-crank lever 94 to which the other end of said rod 95 is connected, the vertical rod 93 connected with said lever 94, the pivoted lever 92 to which the upper end of said rod 93 is connected, and means carried by the car for engaging under proper conditions said lever 92 and causing the latter to effect the operation of said lever 96; substantially as set forth.

14. The car, the cushioning-cylinder thereon having the downwardly-projecting piston-rod, the pivoted plate 98 carried by the car, the rod 71 pivoted to said plate, the arm 75 carried to said rod, the pivot-arm engaging said plate, and means for raising said plate when said pivot-arm is released therefrom for the purpose of projecting the arm 75 beyond the edge of said car, combined with steps normally out of the path of said piston-rod, and means operable from said car when the latter is projected outward for effecting the movement of said steps into the path of said piston-rod; substantially as set forth.

700,459. EDGE-TRIMMING MACHINE. ARTHUR A. TOWNE, BOSTON, Osh. Filed May 13, 1901. Serial No. 80,000. (No model.)

Claim.—1. The combination with a suitable framework, of a guide-track having vertical flanges forming a way adapted to receive edgewise the article to be trimmed, means for causing the article to travel along the track in a plane substantially vertical, and a vertically-adjustable edge-trimming wheel arranged to engage the article during such movement, and means for adjusting said wheel.

2. In an edge-trimming machine, the combination of a supporting guide-track provided with a way adapted to support the article to be trimmed in a substantially vertical plane, vertical feed-rollers located adjacent the track and arranged to cause the article to be trimmed, to travel along said track, a vertically-adjustable edge-trimming wheel located in the plane of the track-guideway, means for adjusting said wheel, and a movable support for the said wheel whereby the latter may accommodate itself to articles of varying width.

3. In a machine of the class described, the combination of a guide-track, provided with upwardly-projecting flanges having breaks at intervals, feed-rollers located at said breaks and arranged to cause the article to travel along the guide-track, and an edge-trimming wheel located in the plane of the guide-track.

4. In an edge-trimming machine, the combination of a track having a guideway adapted to support the article to be trimmed in a substantially vertical plane, means for causing the article to travel along said track, a vertically-adjustable maintaining device located in the plane of the guideway, and a vertically-adjustable edge-trimming device located in the same plane, and suitable means for adjusting the maintaining and edge-trimming devices.

5. In an edge-trimming machine, the combination of a track having a vertical guideway, means for causing the article to be trimmed to travel along said guideway in a plane substantially vertical, a vertically-adjustable maintaining-belt arranged in the plane of the track-guideway, vertically-adjustable edge-trimming means also located in the plane of the said guideway and arranged to engage the edge of the article after it leaves the maintaining-belt, and means for adjusting the maintaining and edge-trimming means.

6. In an edge-trimming machine, the combination of a guide-track constructed and arranged to support the article to be trimmed in a substantially vertical plane, a vertically-adjusting yoke, a pulley carried by said yoke and located in the plane of the guide-track, an endless maintaining-belt passed around said pulley, and suitable edge-trimming means located in the rear of the maintaining-belt.

7. In a machine of the class described, the combination of a supporting-guide for the article to be trimmed, means for causing the article to travel along said guide, an edgewise yoke carrying an inclined position, its free extremity being downward, a pulley mounted on the free extremity of said yoke, an endless maintaining-belt passing around the pul-

ley, and a guide-chose connected with the yoke and forming a runway for the maintaining-belt.

8. In a machine of the class described, the combination of a supporting-guide for the article to be treated, means for causing the article to travel along said guide, a swinging arm, a pulley mounted on the free extremity of said arm, a maintaining-belt passing around said pulley, a guide-chose connected with the swinging arm and surrounding the belt forming a runway therefor, the guideway of the chose being open from below to allow the article to engage the belt which is supported from above by the guide-chose.

9. In a machine of the class described, the combination of a supporting-guide-track having vertical flanges forming a guide for the article to be treated, means for causing the article to travel along said track in a substantially vertical plane, an adjustable, vertically-oscillating yoke-arm, a pulley mounted on the free extremity of said arm in the plane of the article to be treated, and a belt passed around the pulley in the plane of the track-guideway.

10. In a machine of the class described, the combination of a supporting-guide-track, means for causing the article to travel along said track in a plane substantially vertical, an endless maintaining-belt traveling in the plane of the article to be treated, said belt being vertically adjustable, means for adjusting the belt, a liquid-receptacle, and a wheel dipping into said receptacle and arranged to engage the belt for moistening purposes.

11. The combination with a suitable frame, of a supporting-guide-track, means for causing the article to travel along said track in a plane substantially vertical, an adjustable, vertically-oscillating arm, and an edge-ironing wheel mounted on said arm in the plane of the article to be treated.

12. The combination with a suitable frame, of a supporting-track mounted thereon, means for causing the article to travel along said track, an oscillating yoke-arm, an edge-ironing wheel mounted on the free extremity of said arm, and a guide-chose connected with said arm, its upper part being closed and normally downwardly inclined from the front toward the rear, to facilitate the raising of the yoke-arm to accommodate itself to articles of different width.

13. The combination with a suitable frame, of a supporting-guide-track mounted thereon, an oscillating yoke-arm mounted on the frame, a guide-chose connected with said arm in the plane of the guide-track, and an edge-ironing wheel mounted on the yoke in the plane of the track.

14. In an edge-ironing machine, the combination with a suitable frame, of a guide-track mounted thereon, said track being constructed and arranged to support the article to be treated in a plane substantially vertical, a vertically-oscillating yoke-arm also mounted on the frame, a set-bolt threaded in the frame and engaging the yoke-arm for purposes of adjustment, and an edge-ironing wheel mounted on said arm in the plane of the article on the track.

15. In an edge-ironing machine, the combination with a suitable frame, of a guide-track mounted thereon, said track being constructed and arranged to support the article to be treated in a substantially vertical plane, two vertically-adjustable edge-ironing wheels mounted in the plane of the article on the guide-track, one in front of the other, and having their edge-ironing peripheries differently fashioned for the purpose set forth, and means for adjusting the edge-ironing wheels.

16. In an edge-ironing machine, the combination with a frame, of a supporting-guide-track mounted thereon, said track being constructed and arranged to support the article to be treated in a plane substantially vertical, and a pair of vertical feed-rollers cooperating with the track, spindles upon which the said rollers are mounted, a hinged bar for one of the spindles, a bushing through which the last-named spindle passes, and a spring engaging said bushing and cooperating with the hinged bar to allow the roller to yield in the performance of its function.

17. In an edge-ironing machine, the combination with a suitable frame, of a supporting-guide-track mounted thereon, feed-rollers arranged in pairs along said track, an endless maintaining-belt arranged in the plane of the guide-track, a guide-chose forming a runway for said belt, an edge-ironing wheel located in the plane of the track, an oscillating yoke-arm upon which said wheel is mounted, and a guide-chose located in the plane of the track and wheel and cooperating with both.

18. In an edge-ironing machine, the combination with a suitable frame, of a guide-track mounted thereon, said track being constructed and arranged to support the article to be treated in a plane substantially vertical, vertical feed-rollers arranged along said track, an endless moving belt located in the plane of the article on the track, edge-ironing wheels also located in the plane of the article on the track, and suitable means for operating the feed-rollers, the belt and the ironing-wheels.

700,460. ROTARY MOTOR. ROSS VAN BUREN, Broun, Ind. Filed Feb. 7, 1901. Serial No. 44,244. (No model.)

Claim.—1. In the improved rotary motor, the combination with an outer cylindrical casing and a shaft extending centrally and loosely through

the same, of an inner cylinder keyed on said shaft, a plurality of rectangular plates secured to the periphery of said inner cylinder, a suitable valve-box made in one piece with the outer casing, a slide-valve movably arranged in said valve-box and normally engaging the periphery of the inner cylinder; a suitable cam mechanism actuated by the shaft to move the slide-valve into its box at a given moment, passages in the slide-valve and in communication with the annular space between the inner cylinder and the outer casing; a fluid-admission tube connected to said passages, a normally closed valve in said tube and adapted to be opened by the pressure of the fluid, and an exhaust-opening in the outer casing, substantially as set forth.

2. In the improved rotary motor, the combination with the outer casing, a smaller inner cylinder rotatably mounted within said casing, and two rectangular plates projecting radially at the periphery of the cylinder and frictionally engaging the inner wall of the outer casing, of a slide-valve normally engaging the periphery of the inner cylinder, a longitudinal bore in said valve and parallel with the longitudinal axis of the cylinder, a plurality of passages leading from said bore and discharging into the space between the inner cylinder and the outer casing, a suitable cam mechanism to actuate the valve at a given moment, a conduit connecting the bore of the slide-valve to a supply of compressed fluid, and a normally closed valve in said conduit and adapted to be opened by the pressure of the fluid, substantially as set forth.

700,461. ELECTRIC RAILROAD-SIGNAL. WILLIAM D. VAN NEMER, Grand Rapids, Mich. Filed June 9, 1901. Serial No. 44,241. (No model.)

Claim.—1. In combination with a block of railway-track, an electric signal at each end of the block, a circuit and cut-out to operate each signal, a series of signals within the block, positive and negative wires to operate the last-named signals, a switch for each and signal to alternately connect the same, and one of the wires for the series of signals, two electromagnets at each switch to respectively shift the same, electric circuits for each magnet-coil, a circuit-closer adjacent to each and signal and in the circuit operating to open the circuit of said signal and to close the circuit of one of said wires, and a second circuit-closer adjacent to each signal, and in the circuit operating to close the circuit of the signal at the other end of the block and open the circuit of one of the said wires, and means for operating the said circuit-closers by the passage of a train, substantially as described.

2. In combination with a block of railway-track, an electric signal at each end of the block, an electric circuit to operate each signal, a switch

to open and close each circuit, an electromagnet and electric circuit to open each switch, an electromagnet and circuit to close each switch, a circuit-closer in each of the circuits to operate the switches, the two circuit-closers for each signal, being located at opposite ends of the block, substantially as described.

3. In combination with a block of railway-track, an electric generator and positive and negative lines connected to the generator, an electric signal at each end of the block, a circuit-closer to operate each signal, a series of signals within the block and connected in parallel between a positive and negative wire forming a circuit-closer, a switch for each and signal adapted to alternately close the said signal-circuit and the circuit through one of said wires, circuit-closers operating to shift the switch and close the said signal-circuit, circuit-closers in said circuit each located near the end of the block remote from the respective signal, and circuit-closers operating to open the said signal-circuit, each being located near the end of the block adjacent to the respective signal, and means for operating the circuit-closers by the passage of trains, substantially as described.

4. In combination with a railway-track, a train, signals, and electric circuits for operating the signals, circuit-closers in said circuits and located near the track, said closers consisting of insulated spring-electrodes, a vertically-movable plate to connect the same, a spring to depress the plate, and a cam-lever connected to the plate, and a shoe on the train adapted to engage the cam-lever and close the circuit, substantially as described.

5. In combination with a block, a train, electrically-operated signals, and electric circuits for operating the signals, an insulated plate between the tracks, insulated spring-electrodes in the circuit and attached to the plate, a vertically-movable belt, a plate on the belt, a spring surrounding the belt and depressing the same, a cam-lever pivoted to the belt and having a rounded lower end engaging the insulated plate, and a shoe on the train to engage the cam-lever and bring the plate in contact with the electrodes, substantially as described.

6. In combination with a track, a train, electrically-operated signals, and electric circuits to operate the signals, circuit-closers in said circuits and located near the track, a shoe on the train engaging and operating said circuit-closers and forming a part of an electric circuit, an electric bell and circuit-closer on the train whereby the bell is caused to ring whenever the shoe contacts a circuit-closer near the track, substantially as described.

7. In combination with a block of railway-track, an electrical generator, a series of electrically-operated signals at intervals within the block, a positive and a negative wire to operate said signals and each independently connected to the generator, means for connecting and disconnecting each wire to the generator, and operated by the passing train whereby one wire is connected and disconnected by trains going in one direction and the other wire connected and disconnected by trains going in the opposite direction, substantially as described.

8. In combination with a block of railway-track, an electric generator and main circuit, a series of electrically-operated signals within the block, a line connected to the positive side of the main circuit and to one side of the signals, a line connected to the negative side of the main circuit and to the other side of the signals, and means for closing the respective lines as a train enters the respective ends of the block, and means for opening the said lines as the said trains leave the track, whereby both lines are connected and the signals operated whenever two trains approach each other within the block, substantially as described.

700,462. BOTTLE-CLOSURE. JAMES H. VAN NEMER, Cambridge City, Ind. Filed Mar. 17, 1902. Serial No. 44,240. (No model.)

Claim.—1. In a bottle-closure, the combination, substantially as set forth, of a bottle having a cylindrical and a subjacent tapering portion in the base of its neck and having the exterior of its neck screw-threaded and having a side outlet-part from the tapering portion of the base, a plug fitting the cylindrical and tapering portion of said base and having in its lower end an axial part and a transverse part adapted to align with the outlet-part of the neck, a cap screwed upon the neck of the bottle and engaging over the top of the plug, and a stem secured into the top of the plug and projecting upwardly therefrom and provided with means by which it and the plug may be rotated.

2. In a bottle-closure, the combination, substantially as set forth, of a bottle having a cylindrical and a subjacent tapering portion in the base of its neck and having the exterior of its neck screw-threaded and having

a side outlet-part from the tapering portion of the base, a plug fitting the cylindrical and tapering portion of said base and having in its lower end an axial part and a transverse part adapted to align with the outlet-part of the neck, a cap screwed upon the neck of the bottle and engaging over the top of the plug, and a stem secured into the top of the plug and projecting upwardly therefrom and provided with means by which it and the plug may be rotated.

3. In a bottle-closure, the combination, substantially as set forth, of a bottle having a cylindrical and a subjacent tapering portion in the base of its neck and having the exterior of its neck screw-threaded and having a side outlet-part from the tapering portion of the base, a plug fitting the cylindrical and tapering portion of said base and having in its lower end an axial part and a transverse part adapted to align with the outlet-part of the neck, a cap screwed upon the neck of the bottle and engaging over the top of the plug, a self-jacket secured upon the tapering portion of the plug, longitudinal ribs upon the tapering portion of the plug and engaging the interior of said jacket, and a projection from the top of the plug to serve in turning the plug.

700,463. INSULATOR FOR ELECTRIC CIRCUITS. WILLIAM J. WALTERS, Boston, Mass. Filed Jan. 20, 1902. Serial No. 44,239. (No model.)

Claim.—The insulator above described with its saucer-shaped body and centrally-projecting sleeve united by ribs integral with the sleeve and saucer.

700,464. MANUFACTURE OF STERILIZED CARBONATED WATER. THEODORE WEYL, Charlottenburg, near Berlin, Germany, assignor to Siemens & Halske, Aktien-Gesellschaft, Berlin, Germany. Filed Feb. 7, 1902. Serial No. 44,238. (No specimens.)

Claim.—1. The process of manufacturing sterilized carbonated liquid, which consists in first introducing into the liquid to be treated, carbonic acid, and then introducing therein steam under constant pressure

until a greater quantity of essence is absorbed than corresponds to the coefficient of absorption at ordinary pressure.

2. The process of manufacturing sterilized carbonated mineral water, which consists in introducing, into the water to be treated, carbonic acid and essence under contained pressure until tested samples show the extinction of organic life, and then, while continuously maintaining the pressure, transferring the water to storage vessels.

700,465. SYSTEM OF DEVICES FOR KEEPING HOTEL ACCOUNTS. JOHN WILLY, Chicago, Ill. Filed Mar. 26, 1901. Serial No. 58,236. (24 model.)

Claim.—1. In a system of devices for keeping hotel accounts, and room and guest records, the combination of a suitable rack having a series of numbered pockets, one for each room, with a permanent room-card adapted to be inserted in each pocket containing information and marks or signs applicable to the room in question, and a guest's card adapted to be inserted in the same pocket and containing information and marks or signs applicable to the particular guest in connection with the room in question, said room-cards and guest-cards of different colors, each of said cards containing matter which distinguishes it from the other cards and assigns it to its peculiar duty or service.

2. In a system of devices for keeping hotel accounts, and room and guest records, the combination of a suitable rack having a series of numbered pockets, one for each room, with a permanent room-card adapted to be inserted in each pocket containing information and marks or signs applicable to the room in question, and a guest's card adapted to be inserted in the same pocket and containing information and marks or signs applicable to the particular guest in connection with the room in question, said room-card cut away at one corner to facilitate the removal of the guest-card, each of said cards containing matter which distinguishes it from the other cards and assigns it to its peculiar duty or service.

3. In a system of devices for keeping hotel accounts, and room and guest records, the combination of a suitable rack having a series of numbered pockets, one for each room, with a series of room-cards, one for each pocket, a series of guest-cards for said pockets where required, and a series of condition-cards for said pockets where required, said cards differing among themselves in color, each of said cards containing matter which distinguishes it from the other cards and assigns it to its peculiar duty or service.

4. In a system of devices for keeping hotel accounts, and room and guest records, the combination of a rack having numbered pockets, one for each room, with a series of room-cards one for each pocket, and a series of condition-cards for said pockets where required, said condition-cards cut away so as when in position to expose a part of the room-card, each of said cards containing matter which distinguishes it from the other cards and assigns it to its peculiar duty or service.

700,466. MINING-MACHINE. HARRIS B. WYLER, Paris, Ark. Filed Apr. 26, 1901. Serial No. 14,997. (No model.)

Claim.—1. A mining-machine comprising a fixed main frame, separate supporting devices adapted for interchangeable connection with the

main frame, and a drill-carriage constructed and arranged for connection with the supporting devices interchangeably for pivotal movement in different planes at angles to each other.

2. Is a mining-machine, the combination with a main frame including rails, of a carrier slidably engaged with the rails, a drill-carriage mounted upon the carrier for pivotal movement, and provided with drill-actuating mechanism comprising a manually-operable element, means connected with said manually-operable element for moving the carriage pivotally and means for advancing the carrier along the rails and including a pedal disposed in proximity to the manually-operable element of the drill-actuating mechanism, whereby one man may operate the drill, swing the carriage and advance the carrier.

3. A mining-machine comprising a drill-carriage having a drill provided with operating means, said carriage being adapted for interchangeable mounting to oscillate in different planes, a reciprocating pawl operably connected with the drilling mechanism, and a rack mounted in operative relation to the pawl for engagement thereby to move the carriage pivotally, said rack being removable to permit pivotal movement of the carriage in a different plane.

4. A mining-machine comprising a drill-carriage having a drill provided with operating means, said carriage being adapted for interchangeable pivotal mounting to oscillate in different planes, opposing racks, opposing pawls adapted for alternate engagement with their respective racks and operably connected with the drilling mechanism for movement over the racks, and means for throwing the pawls alternately into operative relation to their respective racks.

5. A mining-machine comprising a carriage adapted for pivotal movement, a drill mounted upon the carriage for movement therewith and having operating mechanism, opposing racks, opposing pawls operably connected with the drill-actuating mechanism for engagement with the racks to pivotally move the carriage, and means for moving the pawls alternately into engagement with their respective racks.

6. A mining-machine comprising a carriage adapted for pivotal movement, a drill mounted upon the carriage for movement therewith and having operating means comprising a shaft, a lever pivoted upon the carriage and having cam connection with the shaft for oscillation thereby, opposing pawls mounted upon the lever, opposing racks for engagement by the pawls alternately to pivotally move the carriage in opposite directions, and means for moving the pawls alternately into operative relation to their respective racks.

7. A mining-machine comprising a main supporting-frame including uprights and connecting-rails, a carrier slidably engaged with the rails to permit the carrier to be advanced and retracted, separate supporting devices adapted for interchangeable connection with the carrier, and a drill-carriage constructed and arranged for connection with the supports interchangeably for pivotal movement in different planes lying at angles to each other.

8. A mining-machine comprising a main supporting-frame including uprights and connecting-rails, a carrier slidably engaged with the rails to permit the carrier to be advanced and retracted, separate supporting devices adapted for interchangeable connection with the carrier and at both ends thereof, and a drill-carriage constructed and arranged for connection with the supports interchangeably for pivotal movement in different planes at angles to each other.

9. In a drilling mechanism, the combination with a pivotally-mounted drill-carriage and a reciprocating drill mounted therein, of a rack adjacent to the carriage, a cam-shaft mounted in the carriage and provided with a cam, a lever engaged with the cam and having a pawl in operative relation to the rack to rotate the carriage when the lever is actuated, said shaft having means for engagement with the drill to retract it, means for moving the drill forwardly when released by its retracting means, and means for actuating the shaft.

10. In a drilling mechanism, the combination with a pivotally-mounted carriage and a reciprocating drill mounted therein, of racks disposed adjacent to the carriage and having their teeth arranged in opposition, a shaft mounted in the carriage and provided with a cam, a lever pivoted on the carriage and engaged with the cam for oscillation thereby, pawls carried by the lever for alternate engagement with their re-

spective racks, means for actuating the shaft and means for throwing the pawls alternately into operative relation to their respective racks.

11. In a drilling mechanism, the combination with a pivotally-mounted drill-carriage and a reciprocating drill mounted therein, of opposing racks disposed adjacent to the carriage, a shaft mounted in the carriage and provided with a cam, a lever pivoted on the carriage and engaged with the cam for oscillation thereby, a rocker mounted on the lever, pawls pivoted to the lever and having connection with the rocker for movement thereby to alternately engage their respective racks, means for actuating the rocker, a finger on the drill, a crank on the cam-shaft adapted to engage the finger to swing the drill in one direction, means for retracting the drill when released by the crank, operating-levers for the cam-shaft, and hand-levers connected with the operating-levers for retracting the shaft.

12. A mining-machine comprising a reciprocating drill-rod provided with a lug, a trip-shaft having a trip for engagement with the lug to retract the drill-rod, means for retracting the rod, a crank-shaft provided with double cranks, intermeshing gears upon the crank-shaft and trip-shaft, a handle for one element of each crank, and a rocking lever connected with the second element of each crank.

13. A mining-machine comprising a pivoted carriage, a reciprocating drill mounted in the carriage and provided with a lug, a trip-shaft mounted in the carriage and having a trip for engagement with the lug to retract the drill, means for retracting the drill when released by the trip, means for operating the trip-shaft, and means operably connected with the trip-shaft for moving the carriage pivotally.

14. A mining-machine comprising a pivoted carriage, a reciprocating drill mounted in the carriage, a trip-shaft having a trip for engagement with the drill to retract it, means for retracting the drill when released by the trip, a rack, a pivoted lever operably connected with the trip-shaft for pivotal movement thereby, and a pawl carried by the lever in operative relation to the rack to move the carriage pivotally.

15. A mining-machine comprising a main frame including upper and lower members and uprights removably connected thereto, said uprights having pivot-bearings, a removable pivot-rod engaged with the upper and lower members, and a drill-carriage mounted on the rod removably and adapted for pivotal connection with the uprights.

16. A mining-machine comprising a main frame including upper and lower members and uprights removably connected thereto, a removable pivot-rod engaged with the upper and lower members, a drill-carriage adjustably mounted on the pivot-rod and removable therefrom, said uprights being adapted for attachment to the side of the carriage and adapted for pivotal connection with the carriage when the pivot-rod is removed.

17. A drill-bit for mining-machines, comprising a rectangular stock having two pairs of diverging teeth at one end thereof, the points of said teeth lying without the planes of the side faces of the stock, each of the teeth being pyramidal in form, having rectangular bases and being disposed with the mutually-adjacent edges of their bases on two lines, lying in the same plane and intersecting each other at right angles, said teeth being clear of one another from base to point, substantially as described.

18. A machine of the class described comprising a main frame, a carrier mounted for longitudinal movement in said main frame, a drill-carriage and removable pivotal supports, disposed at right angles to each other, to mount said carriage on said carrier, whereby said carriage may be pivotally mounted to be swung either horizontally or vertically, substantially as described.

19. In a machine of the class described, the combination of a relatively fixed support, a carrier movable longitudinally thereon, and means including a pedal-lever to advance said carrier, a drill-carriage mounted for pivotal movement on said carrier, and a drill-actuating mechanism in said carrier and having hand-levers, whereby the carrier may be advanced, and the drill operated by a single operator manually, substantially as described.

20. In a machine of the class described, the combination of a relatively fixed support, a carrier movable longitudinally thereon, and means, including a pedal-lever, to advance said carrier, a drill-carriage, mounted for pivotal movement on said carrier, a drill-actuating mechanism in said carriage, and having hand-levers, and means operated by said drill-actuating mechanism, to automatically swing said drill-carriage pivotally, whereby the carrier may be advanced, the drill-carriage pivotally swung, and the drill mechanism simultaneously operated manually by a single operator, substantially as described.

21. In a machine of the class described, the combination of a main frame, a carrier mounted for longitudinal movement in said main frame, a drill-carriage and removable pivotal supports, disposed at an angle to each other, to mount said carriage on said carrier, whereby said carriage may be pivotally mounted to be swung in correspondingly-angled planes, and a reciprocating drill and operating mechanism, thereby, with which said carriage is provided, substantially as described.

22. In a machine of the class described, the combination of a relatively fixed support, a carrier movable longitudinally thereon, means to advance said carrier, a drill-carriage mounted for pivotal movement on said carrier, and a drill-actuating mechanism in said carrier and lever with which said carrier-advancing means and drill-actuating mechanism are provided, whereby they may be operated manually, by a single operator, substantially as described.

700,467. PAPER-BAG-MAKING APPLIANCE. DANIEL ARNOLD, Cleveland, Ohio, assignor to the Union Paper Bag Machine Company, Philadelphia, Pa. Filed Jan. 13, 1902. Serial No. 58,237. (No model.)

Claim.—1. In a paper-bag-making appliance, a mandrel comprising a pair of thin blades disposed contiguously to each other at one portion and thence having a tapering divergence, the width of the blades being equal to that of the plaited tube to be dealt with, and the greatest distance between the blades being in correspondence with the fully-open condition of the tube, said blades having narrowed prolongations from their point of greatest divergence, and said narrowed prolongations having a tapering convergence, substantially as set forth.

2. In a paper-bag-making appliance, a mandrel comprising a pair of thin blades disposed contiguously to each other at one portion and thence having a tapering divergence, the width of the blades being equal to that of the plaited tube to be dealt with, and the greatest distance between the blades being in correspondence with the fully-open condition of the tube, said blades having narrowed prolongations from their point of greatest divergence, and said narrowed prolongations having a tapering convergence, the convergence of said narrowed prolongations beginning at a point some distance forward of the junction between the wide and narrow portions of the blades, substantially as set forth.

700,468. MACHINE FOR COVERING SHEETS OF THINER WITH METAL. WILLIAM P. APPELHANS, New Haven, Conn., assignor to Daniel Finkel Co. and Loring Company, a Corporation of New Jersey. Filed Dec. 22, 1901. Serial No. 17,383. (No model.)

Claim.—1. In a machine of the character described, the combination with a suitable frame, of a pair of sheath-formers mounted in the forward part thereof and adapted to approximately shape the edges of the metal, the upper former being constructed in one piece and the lower former consisting of two dies and an intermediate roller, blades in which said sheath-formers are detachably secured, and means mounted on said frame and adapted to complete the bending and shaping of the edges of said metal, substantially as described.

2. In a machine of the character described, the combination with a suitable frame, of a pair of sheath-formers mounted in the forward part of said frame and located one above the other, an upper former constructed in one piece and removably secured to the upper shaft, a lower former consisting of two dies and an intermediate roller removably secured to the

lower shaft, said rollers being constructed and arranged to bend the edges of a metal strip to approximately fit around the tongue and into the groove of a wooden strip, and means secured to said frame whereby the bending and locking of the metal in the wooden strip are completed, substantially as described.

2. In a machine of the character described, the combination with a suitable frame, of a pair of shaft-formers mounted in the forward part of said frame and adjustable located one above the other, the upper of said formers being constructed in one piece and provided on its surface and near one edge thereof with a head and near its opposite end with a groove, said lower former consisting of two dies and the other with a groove, one of said dies being provided with a flange and the other with a groove, said formers being constructed and arranged to bend the edges of the metal into approximately the shape of a tongue and groove, and means secured to said frame whereby the bending and locking of the edges of the metal are completed, substantially as described.

4. In a machine of the character described, the combination with a suitable frame, of a pair of formers mounted in the forward part of said frame and located one above the other, said formers being constructed and arranged to bend the edges of a metal strip into approximately the shape of the tongue and groove of a wooden strip, a pair of rollers mounted in said frame and back of said formers and located one above the other, the upper of said rollers being provided on its ends with downwardly-projecting flanges, and the lower roller having its surface provided with teeth or corrugations, and means secured to said frame whereby the bending and locking of the edges of the metal strip to the wooden strip are completed, substantially as described.

5. In a machine of the character described, the combination with a suitable frame, of a pair of shafts adjustably mounted in the forward part of said frame and located one above the other, rollers removably secured to said shafts, a stationary guide-chase secured to said frame and back of said shafts, and provided on its edges with downwardly-extending flanges and at one corner with a wedge-shaped strip, a pair of shafts adjustably mounted in said frame in the rear of said guide-chase and located one above the other, rollers secured to said last-mentioned shafts, and means secured to said frame whereby the bending and locking of the edges of the metal strip are completed after passing between said rollers and under said guide-chase, substantially as described.

6. In a machine of the character described, the combination with a suitable frame, of a pair of shaft-formers located in the forward part of said machine and one above the other, said formers being vertically adjustable toward or away from each other, a pair of rollers located in the rear of said shaft-formers and one above the other, said rollers being vertically adjustable toward or away from each other, a pair of horizontal rollers mounted on the rear end of said frame and horizontally adjust-

able toward or away from each other, and means secured to said frame and between said rollers whereby the latter are assisted in bending, shaping and locking the edges of the metal strip, substantially as described.

7. In a machine of the character described the combination with a suitable frame, of a pair of rollers mounted in said frame and adapted to partially shape both edges of the metal, a stationary guide-chase adapted to bend downwardly one of said shaped edges of the metal strip, a second pair of rollers adapted to bend downwardly both edges of said metal, a stationary guide-chase located in the rear of said last-mentioned rollers and adapted to continue the bending of both of said edges of said metal, a third pair of rollers adapted to partially lock said shaped edges of the metal around the edges of the timber, and stationary guides located in the rear of said machine and adapted to completely lock the edges of said metal around the edges of said timber, substantially as described.

8. In a machine of the character described, the combination with a suitable frame, of several pairs of rollers adjustably mounted in said frame and adapted to partially bend, shape and lock the edges of the metal, a forward guide-chase secured to the frame and in the rear of the first pair of said rollers, said chase being provided with a downwardly-extending projection at one edge thereof for bending the corresponding edge of the metal strip, a rear guide-chase provided with shoulders adapted to bend both edges of said metal, and guide-formers located in the rear of said rollers and adapted to assist in locking the metal to the timber, substantially as described.

700,469. BLOW-OFF NOZZLE FOR PAPER-MILL MACHINERY.
JAMES H. BAKER, Saratoga Springs, N. Y., assignor to Baker and Sherrin Company, a Corporation of New York. Filed Sept. 16, 1901. Serial No. 74,672. (No model.)

Claim.—1. A blow-off nozzle for paper-mill machinery, comprising a cast body adapted to be connected in the line of piping from the pulp-digester to the blow-tank and having an opening in the surface thereof and a bend passing down into the cast body through said opening with the orifice of the bend in the center of the cast body and set toward the blow-tank, and means for connecting the bend to the cast body and for connecting to the bend a pipe for supplying water, substantially as set forth.

2. A blow-off nozzle for paper-mill machinery comprising a cast body having flanged ends and tapered toward the ends with the openings in the ends of different apertures, an opening in the side of the body, and a flange around the opening, a bend passing through said opening and having a flange resting on the lower flange with the orifice of the bend coming at the center of the cast body and opening in the direction toward the larger end of the cast body and toward the pipe extending to the blow-tank, and means for connecting the bend to the cast body and for connecting to the bend a supply-pipe for water, substantially as set forth.

3. A blow-off nozzle for paper-mill machinery, comprising a cast body having flanged ends and tapered toward the ends with the openings in the ends of different apertures, an opening in the side of the body and a flange around the opening, a bend passing through said opening and having a flange resting on the lower flange with the orifice of the bend coming at the center of the cast body and opening in the direction toward the larger end of the cast body and toward the pipe extending to the blow-tank, and a double-flanged nipple resting upon the flange of the bend and bolts for connecting the parts together, and a pipe for supplying water to the bend connected in the double-flanged nipple, substantially as set forth.

700,470. SHIFTING DEVICE FOR PIERES, &c. WILLIAM D. BALDWIN, New York, and AUGUST BUNDE, Yonkers, N. Y., assignors to Otto Elevator Company, East Orange, N. J., a Corporation of New Jersey. Filed Dec. 17, 1901. Serial No. 88,388. (No model.)

Claim.—1. The combination with the footway of a pier or embankment, of a capstan connected with a shaft extending downward through said footway, a motor connected to operate said shaft and provided with a

control device for stopping, starting, and reversing the motor, and a stopping and starting device having projections extending upward through the footway in different positions, substantially as and for the purpose set forth.

2. The combination with the footway of a pier or embankment, of a capstan arranged above the footway, a shaft connected to the capstan extending below the footway, a motor connected to rotate said shaft and provided with stopping, starting, and reversing means, and a stopping and starting device arranged to be actuated by the foot of the operator upon the footway, substantially as and for the purpose set forth.

700,471. MANUFACTURE OF NITROCELLULOSE AND GASEIN COMPOUND. CHARLES BERNARD, Paris, France. Filed Feb. 4, 1902. Serial No. 92,712. (No specimens.)

Claim.—1. The herein-described process of producing a homogeneous compound of nitrocellulose and cascin, which consists in forming a plastic mass of the cascin in one of its solvents, the latter being an aqueous solution, replacing the water, in part, from the said plastic mass with a liquid solvent of nitrocellulose, then removing the excess of liquid from the plastic mass, and finally incorporating with the mass of cascin a mass of plastic nitrocellulose and kneading the same to form a homogeneous compound.

2. The herein-described method of producing a homogeneous compound of nitrocellulose and cascin, which consists in forming a plastic mass of the cascin with an aqueous solution of borax, then removing the surplus water, then immersing the mass in alcohol to displace a part of the water absorbed by the cascin, then removing the excess of liquid from the mass, then incorporating the mass of cascin thus prepared with a mass of plastic nitrocellulose and kneading the whole into a homogeneous compound.

3. The homogeneous compound of nitrocellulose and prepared cascin above described.

700,472. APPARATUS FOR TREATMENT OF GRAIN PREPARATORY TO GRINDING. GUGLIELMO RANIERI, Milan, Italy. Filed May 18, 1900. Serial No. 717,900. (No model.)

Claim.—1. In an apparatus of the kind specified, a vessel provided with a central feed, and an inclined lid or cover, means for causing the grain to pass centrally downward within said vessel and upwardly along the sides thereof, means for throwing the grain upwardly against said lid, a peripheral channel at the upper end of said vessel provided with outlet-pipe, and means for moving the grain within said channel toward said pipe.

2. In an apparatus of the kind specified, a vessel provided centrally with a tube extending into its upper end, a central shaft provided with a screw adapted to move the grain centrally toward the bottom of the vessel, blades upon the lower face of said vessel, a peripheral channel at the upper end of said vessel provided with outlet-pipe, a rotatable wing or fan at the upper end of said vessel, a central lid or cover on said vessel,

and a rotatable scraper situated within and adapted to traverse said peripheral channel.

700,473. WATCHCASE. EDWARD BLAY, Brooklyn, N. Y., assignor to Dubois Watchcase Company, Brooklyn, N. Y., a Corporation of New York. Filed Jan. 20, 1902. Serial No. 91,555. (No model.)

Claim.—1. In a watchcase, the combination with a movement-ring provided with two grooves, and with a separating flange or head, of a head snapping into one of said grooves, a lock lid hinged to said movement-ring and snapping into the other of said grooves and over and upon said separating-flange, a front lid hinged to said movement-ring and having its edge fitting against the edge of said lock lid, and lock and fly springs contained within said movement-ring and having their ends projecting through the latter to engage with said front lid, substantially as described.

2. In a watchcase, the combination with a movement-ring provided with two grooves, and with a separating flange or head, of a head snapping into one of said grooves, a lock lid hinged to said movement-ring and snapping into the other of said grooves and against said separating-flange, a front lid hinged to said movement-ring and having its edge fitting against the edge of said lock lid, a pendant secured to said movement-ring opposite said hinge, and lock and fly springs contained within said movement-ring, the former being provided with a lock fitting in a recess formed in the edge of said movement-ring at one side of the pendant, and the latter with a lip or projection extending through an opening formed in said movement-ring opposite the pendant, substantially as described.

700,474. RIVETING-BELT FEED OR CARRYING APPARATUS. EDWARD H. BUNCE, Monticello, N. J., assignor of one-half to Fred S. White, Monticello, N. J. Filed Jan. 9, 1902. Serial No. 85,581. (No model.)

Claim.—1. An apparatus of the class described provided with a plurality of carrying-rollers between some of which said over or around others of which an endless belt is passed, and a supplemental guide-roller over which the said belt is passed and one end of which is provided with a swiveling support and the other end of which is mounted in a swiveling support, substantially as shown and described.

2. An apparatus of the class described provided with a plurality of carrying-rollers between some of which said over or around others of which an endless belt is passed, and a supplemental guide-roller over which the said belt is passed and one end of which is provided with a swiveling support and the other end of which is mounted in a swiveling support, said swiveling support being provided with a flexible clamp which is passed over one of the carrying-rollers adjacent thereto, and said roll-

are being provided with a band, at their ends, against which said strap rests, substantially as shown and described.

3. An apparatus of the class described provided with a plurality of carrying-rollers between some of which and over or around others of which an endless belt is passed and a plurality of belt-retaining rollers over which the belt is passed, one end of said belt-retaining rollers being mounted in a swinging support, and said swinging supports being provided with flexible straps which are passed over a carrying-roller adjacent thereto, and said carrying-rollers being provided with a flexible band against which said strap rests, substantially as shown and described.

4. An apparatus of the class described provided with a plurality of carrying-rollers, a belt mounted thereon and a belt retaining or guiding roller over which the belt is passed, one end of the belt retaining or guiding roller being mounted in a swinging support, and the other end thereof in a curved support, and said swinging support being provided with a flexible strap which is passed over the carrying-roller adjacent thereto, said carrying-roller being provided with an elastic band, at the end thereof, against which said strap rests, substantially as shown and described.

700,475. HYDROCARBON-LAMP. THOMAS M. BLAIR, Northboro, Mass. Filed Feb. 7, 1902. Serial No. 704,795. (No model.)

Claim.—1. The combination is a hydrocarbon-lamp, of a vaporizing-chamber, a burner arranged to be fed by vapor from said vaporizing-chamber, a pipe connected to the vaporizer to supply oil thereto, a valve controlling the flow of oil in said pipe, and a diaphragm exposed to the pressure generated in the vaporizing-chamber, and connected to operate said valve to increase the flow as said pressure falls and to diminish said flow as the pressure increases.

2. The combination is a hydrocarbon-lamp, of a burner, a vaporizing-chamber, a pipe connected to the vaporizer to supply oil thereto, a valve controlling the flow of oil in said pipe, and a diaphragm forming the top of the vaporizing-chamber, and connected to operate said valve to increase the flow as the pressure in the vaporizing-chamber falls, and to diminish said flow as the pressure increases.

3. The combination is a hydrocarbon-lamp, of a burner, a vaporizing-chamber, a regulating-valve automatically controlling the supply of oil to the vaporizing-chamber, a pipe or tube between the vaporizing-chamber and burner, a valve controlling the passage of vapor through said pipe, and operating means for closing both valves to shut off the supply to the vaporizing-chamber and the passage of vapor to the burner, substantially as described.

4. The combination is a hydrocarbon-lamp, of a vaporizing-chamber, a burner arranged to be fed by vapor from said vaporizing-chamber, a pipe connected to the vaporizer to supply oil thereto, a valve controlling the flow of oil in said pipe, means operating from the pressure generated in the vaporizing-chamber for controlling the valve, and thereby the supply of oil, and operating means for positively closing said valve.

5. The combination is a hydrocarbon-lamp, of a burner, a vaporizing-chamber, a supply-pipe, a regulating-valve automatically controlling the supply of oil for the vaporizing-chamber, a connection between the vaporizing-chamber and burner, a valve controlling the passage of vapor through said connection, and suitable operating means arranged to open and close both valves, so that when the valves are open, the valve controlling the supply will be free to work, to automatically regulate the supply of oil, substantially as described.

6. The combination is a hydrocarbon-lamp, of a burner, a vaporizing-chamber located above the burner, a tube extending from the chamber to the burner, a mantle arranged around the tube, a valve controlling the supply admitted to the vaporizing-chamber, a rod extending from said valve through said tube, and operating means at the bottom of the lamp for said rod, substantially as described.

7. The combination is a hydrocarbon-lamp, of a burner, a vaporizing-chamber, a tube extending from the chamber to the burner, a mantle arranged around the tube, an automatically-operating valve controlled by the pressure in the chamber for regulating the supply of oil, a rod extending from said valve through said tube, and operating means at the bottom of the lamp arranged to open and close said valve, and to leave said valve, when open, free to automatically operate, substantially as described.

8. The combination is a hydrocarbon-lamp, of a burner, a vaporizing-chamber, a tube extending from the chamber to the burner, a mantle arranged around the tube, a valve controlling the supply to the chamber, a rod extending from said valve through said tube, and operating means for said rod at the bottom of the lamp, substantially as described.

9. The combination is a hydrocarbon-lamp, of a burner, a vaporizing-chamber, a tube extending from the vaporizing-chamber to the burner, a mantle arranged around the tube, an automatically-operating valve controlled by the pressure in the chamber for regulating the supply of oil, a valve controlling the passage of vapor from the chamber to the burner, a rod extending from said valve through said tube, and operating means for said rod arranged to open and close said valve, and to leave the oil-supply valve free to automatically operate when open, substantially as described.

10. The combination is a hydrocarbon-lamp, of a vaporizing-chamber, a cylinder flexibly connected to the oil-supply, and movably mounted in said chamber, a valve, and a diaphragm connected to said cylinder.

11. The combination is a hydrocarbon-lamp, of a vaporizing-chamber, a cylinder flexibly connected to the oil-supply, a valve, a diaphragm connected to move said cylinder, and positive operating connections for said valve.

12. The combination is a hydrocarbon-lamp, of a vaporizing-chamber, a cylinder arranged in said chamber, and flexibly connected to the oil-supply, a yoke carrying two valves, one engaging the cylinder, and the other regulating the passage of vapor from the chamber, and operating means for said yoke, substantially as described.

13. The combination is a hydrocarbon-lamp, of a vaporizing-chamber, a cylinder therein flexibly connected with the oil-supply, a diaphragm connected to said cylinder, a yoke carrying two valves, one engaging said cylinder, and the other controlling the passage of vapor from the vaporizing-chamber, and operating means for said yoke, substantially as described.

14. The combination is a hydrocarbon-lamp, of a vaporizing-chamber, a cylinder therein flexibly connected with the oil-supply, a diaphragm connected to said cylinder, a tube extending from said chamber, a yoke carrying two valves, one engaging said cylinder, and the other engaging the end of said tube, and operating means for said yoke extending through the tube, substantially as described.

15. The combination is a hydrocarbon-lamp, of a vaporizing-chamber, a movable cylinder therein flexibly connected with the oil-supply,

and having a valve-seat on top thereof, and a valve seated therewith and having a pin projecting into said cylinder, substantially as described.

16. The combination is a hydrocarbon-lamp, of a vaporizing-chamber, a cylinder arranged therein, and flexibly connected to the oil-supply, a diaphragm connected with said cylinder, a yoke carrying two valves, one engaging said cylinder, and the other controlling the passage of vapor from said chamber, a tube extending from said chamber, a rod extending through said tube and connected to said yoke, and an operating-handle at the bottom of said tube, substantially as described.

17. In a vapor-burning lamp, on oil-tank, a vaporizer connected to receive oil therefrom, and a burner arranged to be fed by vapor from said vaporizer, and to heat said vaporizer, in combination with a regulating-valve controlling the flow of oil from the tank into the vaporizer, and a regulator for said valve controlled by the varying pressure of vapor in the vaporizer for moving the valve to increase the flow as said pressure falls, and to diminish said flow as the pressure increases.

700,476. PEA-SHELLING MACHINE. THEODORE BOHMER, Brooklyn, N. Y. Filed Sept. 10, 1901. Serial No. 71,571. (No model.)

Claim.—1. In a pea-shelling machine, the combination with the case and the conveyor or endless belt, rollers therefor and means for operating the conveyor, of a hopper, a feeding-cylinder journaled in the hopper, and a device pivotally connected to and extending across the hopper and having its free edge adjustable in relation to the cylinder for regulating the delivery-opening at the base of the hopper and a stirrer-rod extending over the upper edge of the hopper and movable over the surface of the pivotally-connected device, substantially as and for the purposes set forth.

2. In a pea-shelling machine, the combination with a case, a conveyor or endless belt, rollers around which the case passes, and means for operating the conveyor, of a hopper, a cylinder transversely of the hopper and journaled therein and having projections from the surface thereof, which open the upper edge of the case receiving the hopper and on which the hopper moves longitudinally of the case, pulleys upon the shaft of the cylinder and the shaft of one roller of the conveyor and a belt around the pulleys and an adjusting-cover or equivalent device for moving the hopper bodily upon the case and applying tension to the belt, substantially as set forth.

3. In a pea-shelling machine, the combination with a case, of a conveyor or endless belt, rollers therefor, rolls for slipping the pods, gears connecting said rolls and connecting the same with one roller of the conveyor, bearing-plates let into the sides of the case and in which the said rolls and roller at one end of the conveyor are all journaled, whereby said parts are collectively held to the sides of the case and may be bodily removed therefrom, substantially as set forth.

4. In a pea-shelling machine, the combination with the case, a conveyor or endless belt, rollers therefor, rolls for engaging the pods and means for connecting and operating the parts, of a roller having radially-placed flexible blades notched at spaced-apart intervals, a support therefor and a gear connecting the same operatively with the roller, substantially as set forth.

5. In a pea-shelling machine, the combination with the case, a conveyor or endless belt, rollers therefor, rolls for engaging the pods and means for connecting and operating the parts, of a roller having radially-placed flexible blades notched at spaced-apart intervals, a support therefor and a gear connecting the same operatively with the roller, a cover over said roller, a transverse bar adjacent thereto

and fingers extending from the transverse bar and acting to turn the pods on the conveyor and the bar to arrange the pods into single depth so that the pods are presented uniformly to the said roller, substantially as set forth.

6. In a pea-shelling machine, the combination with the case, a conveyor or endless belt, rollers therefor, rolls for engaging the pods and means for connecting and operating the parts, of flanged side plates, a roller journaled in said side plates and having a gear on the end meshing with the gears of the operative rolls, said roller having longitudinal radially-placed flexible blades notched at spaced-apart intervals, a transverse bar secured between the said side plates, separator-fingers at right angles to said bar and lengthwise of the case between the sides thereof, substantially as and for the purposes set forth.

7. In a pea-shelling machine, the combination with the case, a conveyor or endless belt, rollers therefor, rolls for engaging the pods and means for connecting and operating the parts, of flanged side plates, a roller journaled in said side plates and having a gear on the end meshing with the gears of the operative rolls, said roller having longitudinal radially-placed flexible blades notched at spaced-apart intervals, a transverse bar secured between the same side plates, separator-fingers at right angles to said bar and lengthwise of the case between the sides thereof, and pins 21 on the sides of the case for engaging the said side plates at one end, and latch-bars pivotally connected to the sides and adapted to engage the flanged side plates at their other ends for connecting the same to the case of the machine, substantially as set forth.

700,477. COMBINED SKIRT AND DRAWERS. LILLIAN A. BOWMAN, San Francisco, Cal. Filed July 31, 1901. Serial No. 70,491. (No model.)

Claim.—1. An undergarment consisting of a pair of drawers and a back skirt disposed entirely at the rear of the drawers, the latter and said back skirt having a common body portion.

2. An undergarment consisting of a pair of open drawers, and an undivided skirt member arranged solely at the back thereof, said drawers and back skirt member constituting parts of the same pattern-piece and having a common body portion.

3. An undergarment consisting of a pair of open drawers and a back half-skirt combined, the same being formed from a pattern-piece having front drawers forming crotch and crotch and lapped from the waist-line to a point between the legs.

4. An undergarment consisting of a pair of open drawers and a back half-skirt member combined, said drawers and half-skirt member being formed from a pattern-piece having front drawers forming crotch and crotch, lapped and bound from the waist-line to a point between the legs and down to the point where the trimming on the skirt begins.

5. An undergarment consisting of a pair of open drawers having a closed front, and an undivided back half-skirt formed from a single piece of goods.

6. An undergarment consisting of a pattern-piece having a back half-skirt member extended into outer and inner leg-crotch and to form complete drawers including body portion and legs disposed in front of and uncovered by the skirt member, the latter hanging on a bias fold extending from the waist of the drawers-legs to the waist-line of the garment.

700,478. SLIPEE-HOLDER. HERMAN C. GARDNER, Westland, Iowa. Filed Jan. 17, 1902. Serial No. 93,527. (No model.)

Claim.—1. An improved article of manufacture, the slipee-holder consisting of a spring-band divided transversely and having its edges provided with sections arranged diagonally opposite each other, the outer

sides of the band being beveled at each notch; and the under side of the band being left flat opposite each notch, as shown and described.

2. The improved sleeve-holder consisting of a spring-steel band divided transversely and having its edges provided with notches which are curved and form obtuse angles with the intervening straight portions, the latter being directly opposite the notches on the other side of the band, as shown and described.

700,479. CASH-REGISTER. THOMAS GARNETT, Dayton, Ohio, assignor to the National Cash Register Company, Jersey City, N. J., a Corporation of New Jersey. Filed Sept. 3, 1900. Serial No. 28,414. (No model.)

Claim.—1. In a cash-register, the combination with a series of amount or value keys, of racks operated by said keys, a counter mounted on a movable frame and normally disengaged from said racks, a special key and connections for positively throwing the counter into operative engagement with the racks and means for compelling the operation of the special key before the operation of the amount or value keys.

2. In a cash-register, the combination with a counter mounted on a movable frame, of a series of value-keys and connections for operating said counter, means for throwing the counter out of operative engagement with said connections upon each operation of the machine, and a special key which must be operated before each operation of the machine to positively move the counter into operative engagement.

3. In a cash-register, the combination with a counter mounted on a movable frame, of a series of keys and connections for operating said counter, means for throwing the counter out of operative position upon each operation of the machine, a special key arranged when operated to positively move the counter into operative relation with the key connections, and a lock for the key connections operated by said key.

4. In a cash-register, the combination with a series of operating-keys, of a series of racks operated by the same, a counter mounted on a movable frame and arranged to be moved into connection with said racks, a special key, and a clotted lever operated by said key and engaging a projection of the counter-frame.

5. In a cash-register, the combination with a series of operating-keys, of a series of racks operated thereby, a counter mounted on a movable frame and arranged to be moved into connection with said racks, a pin on said counter-frame, a lever having a cam-disk into which said pin projects, and a special key for operating said lever to throw in the counter.

6. In a cash-register, the combination with a series of operating-keys and connections, of a series of racks operated by the same, a counter mounted on a movable frame and arranged to be moved into connection with said racks, a cam-disk lever arranged to engage said frame for throwing the counter, a key for operating said lever and a latch for said lever controlled by the key connections.

7. In a cash-register, the combination with a series of operating-keys, of a series of racks operated by the same, a counter mounted on a movable frame, a rotation-shaft, connections between the keys and shaft, a special key for positively throwing the counter into engagement with the racks, and a latch for the rotation-shaft arranged to be operated by the special key to unlock the operating-keys.

8. In a cash-register, the combination with a series of operating-keys, of a series of racks operated by the same, a counter mounted on a movable frame and arranged to be moved into connection with the racks, a lever for throwing said frame, a key for operating said lever, a latch for holding said lever in its operative position and a lock for said lever.

9. In a cash-register, the combination with a series of amount or value keys and connections, of a series of racks operated thereby, a counter mounted on a movable frame and arranged to be thrown into connection with said racks, a lever for throwing said counter, a key for operating said lever, a pin mounted on said lever, a locking-lever co-operating with said pin to release the key connections and to act as a detent for the throwing-lever.

10. In a cash-register, the combination with an operating mechanism, of a counter arranged to be thrown into connection therewith, a cam-disk lever arranged to throw said counter, a key for operating said lever and means for preventing two operations of the lever during a single operation of the operating mechanism.

11. In a cash-register, the combination with an operating mechanism, of a counter, a rotation-shaft independent of the counter and carrying a cam, a lever for throwing the counter into engagement with the operating mechanism, and a lock for said lever arranged to be operated by said cam.

12. In a cash-register, the combination with an operating mechanism, of a counter, a lever for throwing the counter into engagement with the operating mechanism, a stop-lever for preventing the operation of said throwing-lever, a lock-lever arranged to act as a detent for the throwing-lever, and means for operating said lever.

13. In a cash-register, the combination with a series of keys, of a series of racks operated thereby, a counter mounted on a movable frame and arranged to be brought into engagement with said racks, a pin on the counter-frame, a pivoted lever having a cam-disk into which said pin projects, and a key for operating said lever.

14. In a cash-register, the combination with a series of keys, of a series of racks operated thereby, a counter mounted on a movable frame and arranged to be moved into connection with said racks, a pin mounted on the counter, a throwing-lever having a cam-disk into which said pin projects, a pin mounted on said throwing-lever and two spring-drawn levers co-operating with said pin, one for locking the pin in its elevated position and the other for preventing its elevation.

15. In a cash-register, the combination with an operating mechanism, of a counter arranged to be moved into connection therewith, a pivoted lever for throwing said counter, and a latch-lever arranged to engage and alternately lock the throwing-lever and the operating mechanism.

16. In a cash-register, the combination with a series of operating-keys, of a series of racks operated thereby, a counter mounted on a movable frame and arranged to be moved into connection with the racks, a pivoted lever for throwing said frame, a lock-lever for temporarily holding said pivoted lever against operation and a lock-lever for holding said pivoted-lever in its normal position when operated.

17. In a cash-register, the combination with a counter, of a series of operating-keys and connections for operating said counter, a special key and cam-lever for throwing in the counter upon the operation of the key, and a detent means for holding the cam-lever in its operative position arranged to be operated by a movable part of the machine.

18. In a cash-register, the combination with a series of amount or value operating keys, of counter-operating devices co-operating therewith, a counter arranged to be thrown into connection with said devices, a special key and connections for so throwing said counter when said special key is operated, and a latch for preventing operation of the value-keys until said special key and connections are fully operated.

19. In a cash-register, the combination with a counter pivoted with a projecting lug, of a series of value-operating keys, and connections for operating the counter, a special key, and a lever connected to said key and having a cam-disk to rotate the counter-lug for positively throwing the counter into operative position.

20. In a cash-register, the combination with a counter, of a series of operating-keys and connections for operating the counter when said keys are operated, spring-operated means for throwing the counter out of operative position upon each operation of the machine, and a special key which must be operated before each operation of the operating-keys to bring the counter into operative position.

21. In a cash-register, the combination with a counter mounted on a movable frame, of a series of keys and connections for operating said

counter, a special key for positively throwing the counter into operative position, means for turning the counter to zero and devices arranged to be operated by said means for locking the counter in its inoperative position.

22. In a cash-register, the combination with a series of amount or value keys, of operating devices controlled by the keys, a counter arranged to be brought into engagement with said operating devices, devices for normally locking the amount or value keys, and a special key arranged to bring the counter and operating devices into operative engagement and to unlock the amount-keys.

700,480. MACHINE FOR MAKING SPOOL-BLANKS. JAMES W. CHAMBER, Auburn, Me. Filed Aug. 14, 1900. Serial No. 28,392. (No model.)

Claim.—1. An organized machine for forming spool-blanks and the like, comprising, essentially, guides for stock prepared in stick form, the reciprocating trough-shaped feeder provided with dogs to engage the stock within said feeder in the advance of the feeder, the outer-head to shape the end portion of the stick, the tool to form the central hole in each end portion, the movable clamp members to engage with the stock adjacent the outer-head, cam mechanism to operate the said movable clamp members, and means to cover the finished blank, substantially as described.

2. An organized machine for forming spool-blanks and the like, comprising, essentially, guides for stock prepared in stick form, the reciprocating trough-shaped feeder provided with dogs to engage the stock within said feeder in the advance of the feeder, the outer-head to shape the end portion of the stick, the tool to form the central hole in each end portion, the movable clamp members to engage with the stock adjacent the outer-head, cam mechanism to operate the said movable clamp members, the supplementary clamp to engage the fresh piece of stock within the said feeder and hold the same during the return movement of the feeder and means to cover the finished blank, substantially as described.

3. An organized machine for forming spool-blanks and the like, comprising, essentially, guides for stock prepared in stick form, the reciprocating trough-shaped feeder provided with dogs to engage the stock within said feeder in the advance of the feeder, the outer-head to shape the end portion of the stock, the angler to bore the central hole in each end portion, means to rotate and to advance said outer-head and angler, the movable clamp member to engage with the stock adjacent the outer-head, cam mechanism to operate the said movable clamp members, and means to cover the finished blank, substantially as described.

4. An organized machine for forming spool-blanks, containing, in combination, guides for stock prepared in stick form, the reciprocating feeder, the clamp to hold the stick while being operated upon, the supplementary clamp to hold the fresh stick during the receding movement of the feeder, the outer-head to turn the end portion of the stick, an angler to bore a central hole in each end portion, and a cover to cover the blank from the end of the stick, substantially as described.

5. The combination with the outer-head, and its hollow shaft, of the tube within the said shaft and having the split and with external flange, the angler within the said tube, and means to move the tube endwise within the shaft to compress it upon the angler, substantially as described.

700,481. PORTABLE RIVETING, OR APPARATUS. PATRICK J. CHAMBER, Belfast, Ireland. Filed Apr. 13, 1901. Serial No. 28,397. (No model.)

Claim.—1. In a portable riveting, punching and like apparatus, the combination of a cylinder, a shaft having a hammer-head at its end adapted to be guided in the ends of said cylinder, a piston air-tightly packed in said cylinder, a compression-spring between said shaft and said piston, means for forcing back said shaft intermittently against the action of said spring and piston, and means for holding said apparatus upon the work-piece, substantially as set forth.

2. In a portable riveting, punching and like apparatus, the combination of a support-frame, means for holding said frame upon the work-piece, a shaft having a hammer-head at its end and slidably mounted in said frame, means for imparting a backward movement to said shaft, a cylinder at rear of said shaft, a piston fitting in said cylinder, a compression-spring between said piston and said shaft, an inwardly-opening valve upon said cylinder and a spring in said cylinder at rear of said piston, whereby the piston is caused to rebound after compression, so that air is permitted to enter the cylinder through the valve to replace any that may have escaped during compression.

3. In a portable riveting, punching and like apparatus, the combination of a support-frame, means for holding said frame upon the work-piece, a guide mounted in said support-frame, a shaft having a hammer-head at its end and mounted in said guide, a compression-spring at the rear of said shaft, a piston at the rear of said spring, an air-compression cylinder in which said piston fits, an inwardly-opening valve on said cylinder, and means for intermittently forcing back said shaft against the pressure of the spring and the compressed air.

4. In a portable riveting apparatus comprising a riveter and a holding-up device adapted to be separately held upon the work-piece by non-mechanical means, the combination of a shaft having a hammer-head at its end, an air-compression cylinder, a piston in said cylinder in connection with said shaft, means for intermittently forcing back said shaft against the action of said piston, means for forcing forward said shaft after each backward movement, a holder in said holding-up device, means for pressing forward said holder, and an air-chamber behind said holder whereby it is forced toward the work-piece to support the rivet.

5. In the holding-up device of a riveting apparatus, the combination of a support-frame, means for holding said frame upon the work-piece, a cylinder in said frame, a holder adapted to fit in said cylinder and directly connected with a holding-up head, a spring adapted to force said holder out of said cylinder, and an inwardly-opening valve on said cylinder whereby air may enter to replace any air which may have escaped when the holder was forced backward.

6. In a portable riveting, punching and like apparatus, the combination of a support-frame, a cylindrical guide-chamber / mounted in said support-frame, a shaft having a hammer-head at its end and adapted to slide in said guide-chamber, a spring at rear of said shaft, a piston at rear of

mid spring, a cylinder in which said piston fits, an inlet-valve *j*, and means for intermittently pressing back said shaft against the action of said spring and piston.

7. In a portable riveting, punching and like apparatus, the combination of a support-frame *p*, a cylindrical guide-cylinders *l* mounted to said support-frame, a shaft having a hammer-head at its end adapted to slide in said guide-cylinders, means for imparting a backward movement to said shaft, a spring *g* at rear of said shaft, a piston *h* at rear of said spring, a cylinder in which said piston fits, an inlet-valve on said cylinder, and a spring in said cylinder at rear of said piston *h*, whereby the piston is caused to rebound after a compression so that air may be caused to enter by the valve to replace any air that may have escaped during compression.

8. In a holding-up device for a diving apparatus the combination of a support-frame *u*, a cylinder *v* mounted in said support-frame, a bellows fitting in said cylinder, a holding-up head *a* attached to said bellows, an inwardly-opening valve *f* in said cylinder, and a spring adapted to force said bellows outwardly from said cylinder, whereby the bellows always rebounds in the cylinder after compression and causes air to enter through the valve *f* to replace any air that may have escaped during compression.

700,489. FRANK AND KILL. ARTHUR E. DOWELL, Washington, D. C., and WILLIAM E. HALLIMAN, Pittsburgh, Pa. Filed July 6, 1891. Serial No. 67,312. (No model.)

Claim.—1. The combination in a drier, of a series of tunnels, an uptake at one end of the drier, and means for heating the tunnels; with vapor-flues in the side walls of the several tunnels, opening at bottom into the bottom of the tunnels, and at top into the uptake, substantially as described.

2. The combination in a drier, of a series of tunnels, an uptake at one end of the drier, and means for heating the tunnels and uptake; with downward vapor-flues in the opposite side walls of each one of the tunnels opening at bottom into the bottom of the tunnels, and at top into the uptake, substantially as described.

3. The combination in a drier, of a series of tunnels, an uptake at one end thereof, and valved uptake-outlets connecting the tunnels with the uptake; with downward-flues in the walls and partitions between each one of the tunnels communicating at their lower ends with the bottoms of the tunnels and at their upper ends with the uptake, substantially as described.

4. The combination in a drier, of a series of tunnels, an uptake at one end thereof, valved openings connecting the tops of tunnels directly with the uptake, and means for heating the tunnels; with vertical flues in the side walls of each one of the tunnels communicating at their lower ends with the bottoms of the tunnels and at their upper ends with the uptake, substantially as described.

5. The combination of a series of tunnels an uptake at one end thereof, having a smoke-chamber extending over the tunnels, and means for heating the tunnels; with downward vapor-flues in the partitions between the tunnels below the uptake, and flues communicating at bottom with the bottoms of the tunnels and extending up into the smoke-chamber, for the purpose and substantially as described.

6. The combination of a series of tunnels, an uptake at one end thereof having a smoke-chamber extending over the tunnels, valved openings directly connecting the tops of tunnels with the uptake, and means for heating the tunnels; with vertical vapor-flues in the walls and partitions between each one of the tunnels below the uptake, and flues communicating at bottom with the bottoms of the tunnels and extending up into the smoke-chamber, for the purpose and substantially as described.

7. In a drier, the combination of a series of drying-tunnels, an uptake at one end thereof, and vertical flues in the opposite side walls of each one of the tunnels communicating at top with the uptake and at bottom with the lower portions of the tunnels.

8. In a drier, the combination of a tunnel, a furnace at the discharge end thereof, an uptake at the receiving end thereof and smoke-flues under the tunnel extended to said communicating with the uptake; with opposite vertical flues extending through the vertical division-walls of the tunnel at the receiving end of the drier communicating at their lower ends directly with the lower part of the tunnel, and at top with the uptake, substantially as described.

9. The combination of a series of tunnels, furnaces at one end thereof, an uptake at the other end thereof, and smoke-flues leading from the furnaces to the uptake; with flues extending through the walls and partitions of the tunnels at the uptake end of the tunnel, communicating at bottom with the bottoms of the tunnels and at top with the uptake, substantially as described.

10. The combination of a tunnel, a furnace at one end thereof, an uptake at the other end thereof, and a smoke-flue exterior to the tunnel leading from the furnace to the uptake, and an outlet from the top of the tunnel to the uptake; with vertical flues in the opposite side walls of the tunnel communicating at their lower ends directly with the tunnel near the floor thereof, and at top with the uptake, substantially as described.

11. In a drier the combination of a series of drying-tunnels, an uptake at one end thereof, openings directly connecting the top of the tunnels with the uptake, and vertical flues in the partitions between the tunnels communicating at top with the uptake, and at bottom with the lower portions of the tunnels.

12. In a drier, the combination of a series of tunnels, furnaces at the discharge end thereof, an uptake at the receiving end thereof, openings connecting the top of the tunnels with the uptake, and smoke-flues under the tunnels and extended to and communicating with the uptake; with vertical flues extending through the partitions between the tunnels at the receiving end of the drier communicating at bottom with the lower parts of the tunnels, and at top with the uptake, substantially as described.

13. The combination of a series of tunnels, furnaces at one end thereof, an uptake at the other end thereof, an opening connecting the top of the tunnels with the uptake, and smoke-flues exterior to the tunnels leading from the furnaces to the uptake; with vertical flues located therein the walls and partitions of the tunnels at the uptake end of the tunnels, communicating at bottom with the bottoms of the tunnels and at top with the uptake, substantially as described.

14. The combination of a series of tunnels an uptake at one end thereof having a smoke-chamber extending thereover, and furnaces at the other end thereof, and flues leading under the tunnels from the furnaces and connecting with the smoke-chamber by exterior flues; with vapor-flues in the side walls of each one of the tunnels below the smoke-chamber communicating at bottom with the bottoms of the tunnels, and extending up into the smoke-chamber, substantially as described.

15. The combination of a series of tunnels, an uptake at one end thereof having a smoke-chamber extending thereover, and vertical smoke-flues at the sides of the tunnel communicating with the uptake by extensions at their upper ends; furnaces at and below the other ends of the tunnels, and smoke-flues leading from said furnaces beneath the tunnels and connecting with said vertical smoke-flues; with vapor-flues in the walls of partitions between the tunnels having their lower ends opening into the bottoms of the tunnels, and their upper ends extended upwardly into and communicating with the smoke-chamber, substantially as described.

16. The combination of a series of tunnels, an uptake at one end thereof having a smoke-chamber extending thereover, and furnaces at the other end thereof, and flues leading under the tunnels from the furnaces and connecting with the smoke-chamber by exterior flues, and valved openings in the roof of the tunnels directly connecting the latter with the smoke-chamber; with vertical vapor-flues in the walls of said partitions between the tunnels below the smoke-chamber communicating at bottom with the bottoms of the tunnels, and extending up into the smoke-chamber, for the purpose and substantially as described.

17. The combination of a series of tunnels, an uptake at one end thereof, having a smoke-chamber extending thereover, and vertical smoke-flues at the sides of the tunnel communicating with the uptake by extensions at their upper ends projecting into the smoke-chamber; furnaces at and below the other ends of the tunnels, and smoke-flues leading from said furnaces beneath the tunnels and connecting with said vertical smoke-flues; with valved openings in the roof of the tunnels to allow upward of vapors into the smoke-chamber, and vertical vapor-flues in the walls of and between the tunnels having their lower ends opening directly into the tunnels near the floor thereof, and their upper ends extended upwardly into and communicating with the smoke-chamber, substantially as described.

700,488. EAR-LABEL. HENRY T. BERRY, Salt Lake City, Utah. Filed Aug. 29, 1891. Serial No. 72,715. (No model.)

Claim.—1. An ear-label, comprising a two-membered clip having corresponding perforations, a fastening to be projected through the perforations, one end of the fastening being pointed and adapted to be upset against one outer side of the member, and a tag carried by the opposite end of the fastening.

2. An ear-label comprising a tag, a cutting-ferrule carried thereby, and a combined cyrst and rivet for holding the ferrule assembled with the tag.

3. An ear-label comprising a tag, a cutting-ferrule carried thereby, a rivet for holding the ferrule assembled with the tag, an cyrst on the rivet, and a pendant engaging the cyrst.

4. An ear-label comprising a two-membered tag, a cutting-ferrule carried by one of the members of the tag, and a pointed rivet passing through the ferrule and through the other member of the tag to hold the two members assembled.

5. A device of the character described, consisting of a substantially V-shaped clip having opposite corresponding perforations, a pointed fastening to project through the perforations, one end of the fastening having a head to limit the forward movement thereof, and the opposite end being constructed to be upset against the adjacent outer side of the clip, and means for connecting a tag member to the head end of the fastening.

6. A device of the character described, comprising a substantially V-shaped clip having terminal corresponding slots, one of which is longer than the other, and a flat fastening device to be inserted endwise through the long slot and finally the other slot, the intermediate portion of the fastening being flat and having one end reduced and pointed, the opposite end being enlarged to form a head for limiting the forward insertion of the fastening, the pointed end of the latter being constructed to be upset against the adjacent outer face of the clip.

7. A device of the character described, comprising a substantially V-shaped clip having corresponding terminal perforations, a cutting-ferrule located between the members and aligned with the corresponding perforations, a fastening device to be inserted through the perforations and the ferrule, one end of the fastening being pointed and adapted to be upset against the outer face of the adjacent portion of the clip, and the opposite end of the fastening having a split ring, and a tag having an eye in its engagement with the split ring.

700,484. PUMP-HEAD. HENRY H. BERRY, Marion, Pa. Filed Feb. 12, 1892. Serial No. 65,790. (No model.)

Claim.—1. In pump-operating mechanism, and in combination with a shaft-bar connected with the pump-rod, and a toothed segment co-operating therewith and having an integral cheek with nuts in opposite sides, a handle, and plates secured to opposite sides of the handle and having extended portions provided upon their inner faces with projecting portions to interlock with the nuts in the sides of the abovedescribed cheek by a sliding movement, said handle being readily detachable from the shaft of the toothed segment, substantially as set forth.

2. In pump-operating mechanism, and in combination with a shaft-bar connected with the pump-rod, and a toothed segment having an integral cheek, legs at opposite sides of the said cheek and having their outer ends cut away upon their inner sides to form spaces, and a handle having spaced extensions to interlock with and embrace opposite sides of said cheek and adapted to have the terminal portions of said extensions enter the spaces formed by the cut-away portions of the legs, substantially as specified.

3. In pump-operating mechanism, and in combination with the segment for actuating the pump-rod provided with a cheek, legs secured to opposite sides of the cheek at the inner end thereof and having the sides adjacent to the cheek cut away for a short distance from their outer ends, the side walls formed by the cut-away portions being outwardly inclined, a handle, and plates secured to opposite sides of the handle and having extended portions to embrace opposite sides of the abovedescribed cheek and interlock therewith, the outer sides of the extended parts of the plates being inclined to conform to the inclined side walls of the cut-away portions of the legs, substantially as set forth.

4. In pump-operating mechanism, and in combination with the segment for actuating the pump-rod having an integral cheek, hubs and journals, legs secured to opposite sides of the cheek and having their inner ends rounded to receive a portion of the hubs and having the sides adjacent to the cheek cut away for a short distance from their outer ends, a handle, and plates secured to opposite sides of the handle and adapted to

interlock with the sides of the cheek by a sliding movement and adapted to have their ends enter the spaces formed by the cut-away parts of the legs, substantially as and for the purpose specified.

5. In pump-operating mechanism, and in combination with the segment for actuating the pump-rod and having an integral cheek and integral hubs and journals, legs secured to opposite sides of the cheek and having their inner ends rounded to receive portions of the hubs and having the sides adjacent to the cheek cut away for a short distance from their outer ends, the side walls of the cut-away parts being outwardly inclined, a handle, and plates secured to opposite sides of the handle and having projecting portions to embrace opposite sides of the cheek and interlock therewith and having their outer sides inclined to conform to the inclined walls of the cut-away parts of the legs, substantially as specified.

700,485. FLUSH-VALVE. JAMES J. FINNEY, Chicago, Ill., assignor of one-half to Joseph H. Chandler, Chicago, Ill. Filed Apr. 25, 1892. Serial No. 714,761. (No model.)

Claim.—1. In a flush-valve provided with a piston for opening and closing said valve, the combination with means for adjusting the closing speed of said piston, and means for automatically retarding the latter portion of each closing speed of said piston, of means for maintaining a uniform but reduced flow of water during the retarded portion of the closing movement.

2. In a flush-valve adapted to be connected to a service-pipe and arranged to be operated by the pressure of water in said service-pipe, a valve-body providing an interior chamber, a piston movable in said chamber, and serving to open and close said valve, a passage-way having one end communicating with the water under pressure in said service-pipe and the other end communicating with the chamber over said piston, means whereby a flow of water from the service-pipe through said passage-way will serve to move said piston to a closing position, and means whereby the amount of flow from the service-pipe through said passage-way will be reduced when the piston is near its closing position.

3. In a flush-valve adapted to permit a predetermined amount of flow direct from a service-pipe to a closet-bowl and arranged to be operated by the pressure of water in said service-pipe, a piston serving to close said valve and provided with an opening therethrough, means whereby a flow of water from said service-pipe through said opening serves to move said piston to a closing position, and means whereby the amount of flow from the service-pipe through said opening is reduced when the piston is near its closing position.

4. In a flush-valve adapted to be connected to a service-pipe which supplies water under pressure, a piston arranged to open and close said valve, a passage-way through which water flows under pressure from said service-pipe to said piston to close said valve, means for adjusting the area of said passage-way so as to regulate the flow of water therethrough, and means for automatically reducing the flow through said passage-way during the latter part of the closing movement of said piston.

5. In a flush-valve provided with a chamber and an opening thereto, a piston in said chamber for closing said opening, said piston being provided with a projection on one side and said projection being provided with an opening extending to the opposite side of the piston so as to permit water to flow from one side to the other, and means whereby the amount of flow through said opening is largely reduced during a portion of the time when said projection is entering the opening to said chamber.

6. In a flush-valve mechanism, the combination with a casing having inlet and outlet openings, of a chamber located therein, a piston-valve sliding in said chamber, open passage-ways leading from said chamber at one side of said valve to inlet and outlet openings, lower passage-ways leading from said chamber at the other side of the valve to the inlet and outlet openings, means normally closing one of said lower passage-ways, and means whereby the other of said lower passage-ways is partially closed by said valve at a predetermined point in the closing movement thereof.

7. The above-described flush-valve which consists of a closed chamber containing a sliding piston and a suitable relief-valve and is provided with suitable water-passage leading to both sides of said piston and so arranged that the passage leading to one side is normally open and the passage leading to the other side is partially closed by the piston at a predetermined point during the return of the valve to its rest, whereby the tendency to hammer is overcome, and means substantially as described whereby a uniform afterflow is caused to take place for a predetermined period after the closing of said passage.

8. In a flush-valve mechanism, the combination with a casing having inlet and outlet openings, of a chamber located therein, a piston-valve sliding in said chamber, open passage-ways leading from said chamber at one side of said valve to the inlet and outlet openings, lower passage-ways leading from said chamber at the other side of said valve to the inlet and outlet openings, a relief-valve for opening and closing one of said lower passage-ways, and means whereby the other of said lower passage-ways is partially closed at a predetermined time during the closing movement of said valve.

9. In a flush-valve mechanism, the combination with a casing having inlet and outlet openings, of a chamber located therein, a piston-valve sliding in said chamber, a valve-seat at one end of said chamber, open passage-ways of substantially equal area in cross-section leading from said seat to the inlet and outlet openings, lower passage-ways leading from the chamber at the opposite side of the valve to the inlet and outlet openings, one of which is constantly open, a regulating device in said open lower passage-way, and a relief-valve by which the other of said lower passage-ways is normally closed.

700,486. FLUSH-VALVE. JAMES J. FURRY, Chicago, Ill. Filed Aug. 20, 1898. Serial No. 52,388. (No model.)

Claim.—In a flush-valve provided with a piston for opening and closing said valve, the combination with means for moving said piston so as to maintain during a portion of its closing movement a reduced and uniform flow of water, of means for shutting off such flow of water prior to the final closing action of said piston, substantially as described.

700,486.

700,487. FLUSH-VALVE. JAMES J. FURRY, Chicago, Ill. Filed May 27, 1898. Serial No. 62,071. (No model.)

Claim.—1. In a flush-valve, the combination with a piston for opening and closing said valve, and an enclosing chamber provided with water-passage leading to both sides of said piston and so arranged that the passage leading to one side is normally open and the passage leading to the other side is partially closed during the closing movement of said piston, of an adjustable device for regulating the flow of water through the passage when left open by said piston, and a second adjustable device for regulating the flow of water through the same passage when partially closed by said piston.

2. In a flush-valve, the combination with a piston for opening and closing said valve, and an enclosing chamber provided with two passage-ways extending from a water-supply to the space over said piston and so arranged that one of said passage-ways is automatically closed by the said piston at a predetermined point in its closing movement, of an independently-adjustable device in each passage-way for regulating the flow of water through the said passage-ways.

3. In a flush-valve, a piston arranged to open and close said valve, an adjustable device for regulating the speed of the closing movement of said piston, means for automatically retarding the latter part of said closing movement, and a second adjustable device for regulating the amount of such retardation.

4. In a flush-valve adapted to permit a flow of water from a service-pipe to a closet-bowl, a valve-body provided with passage-way for water whereby the pressure of water in said service-pipe operates to close said valve, a movable piston arranged to open and close said valve, means whereby the closing movement of said piston operates to close the inlet to said passage-way so as to cause a retardation of the valve-closing movement, and an adjustable device whereby the amount of such retardation may be regulated.

5. In a flush-valve adapted to be opened and closed by water-pressure, the combination with a piston arranged to be moved by such pressure so as to cause such opening and closing, and a valve-body in which said piston operates, said valve-body being provided with passage-ways through which the water-pressure acts to close said valve and said passage-ways being located so as to be closed by said piston before the closing of the valve, of means for permitting water to flow to said passage-

way from a different point, and means for regulating the amount of the last-mentioned flow.

700,488. COMBINATION DOOR-KNOB AND KEY. JOHN W. FERRIS, Denver, Colo., assignor of one-half to John R. A. Haynes, Denver, Colo. Filed June 17, 1891. Serial No. 64,912. (No model.)

Claim.—1. In a device of the class described, the combination with the inner and outer knobs and a hollow spindle connecting the same, of a shaft extending through the hollow spindle and projecting entirely through the outer knob and having the threaded outer portion, the exterior rotary thumb-piece 33 having a threaded opening receiving the threaded portion of the shaft, the threaded shaft 34 arranged on the threaded portion of the shaft within the outer knob and extending through the same and abutting against and forming a stop for the exterior thumb-piece, and ball-ringing mechanism connected with the shaft and operated by the same, substantially as described.

2. In a device of the class described, the combination with inner and outer knobs and a connecting-spindle, of a plate arranged within and detachably secured to the inner knob, a bracket mounted on the plate and provided with an opening, a central gear-wheel arranged in the opening, a shaft secured to the central gear-wheel and extending to the outer knob and provided with means for rotating it, an eccentrically-arranged spindle or pivot, a rotary hammer provided with a central piston, an eccentrically-arranged gear-wheel meshing with the central piston and provided with a piston meshing with the central gear-wheel, and a brace supporting the pivot or spindle, substantially as described.

3. In a device of the class described, the combination of the inner knob composed of inner and outer sections, the inner section having its shank interiorly threaded, a plate provided with a threaded stem engaging the said shank, a bracket mounted on the plate and having an opening, a support secured to the bracket and supporting the outer section of the inner knob and provided with a pivot or spindle, a hammer mounted on the pivot or spindle, a gear-wheel arranged in the opening of the bracket, gearing connecting the piston and the said gear-wheel, and a shaft connected with the gear-wheel, substantially as described.

4. In a device of the class described, the combination of the inner and outer sections of the inner knob, the plate detachably secured to the inner section, the bracket mounted on the plate, the longitudinal support secured at its outer end to the outer section of the inner knob and provided at its inner end with a pivot centrally secured to the bracket, a rotary hammer mounted on the pivot, a centrally-arranged gear-wheel arranged within the bracket, an eccentrically-arranged pivot or spindle, an eccentrically-arranged gear-wheel having a piston meshing with the centrally-arranged gear-wheel, a piston carried by the hammer and meshing with the eccentrically-arranged gear-wheel, and the triangular brace mounted on the bracket and supporting the pivot or spindle, substantially as described.

700,489. VEHICLE-WHEEL. DANIEL H. HAYNES, New York, N. Y. Filed Mar. 7, 1898. Serial No. 67,118. (No model.)

Claim.—1. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, the spokes provided at substantially their outer ends with laterally-projecting ears forming bearing-threads, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, guide-plates secured to the said tire-rim and extending laterally over the said resilient ring and hub-rim, and bolts, arranged within the hub-rim and between the said spokes, for securing the said guide-plates together; and a link pivotally connected at one end to one of said spokes and at the other end to one of the said guide-plates, substantially as described.

2. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, the spokes provided at substantially their outer ends with laterally-projecting ears forming bearing-threads, of a combining device, comprising a resilient ring, engaged by the outer face of said rim,

a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, and guide-plates secured to the said tire-rim and projecting laterally over the said resilient ring and hub-rim, and engaging the laterally-projecting ears or bearing-threads of said spokes; and a link connecting the said members together, substantially as set forth.

3. In a wheel, the combination with a tire member comprising a tire-rim, and a tire supported directly thereby upon its outer periphery, of a combining device, comprising a resilient ring, supported directly against the inner periphery of the said tire-rim, an independent hub member comprising a hub, spokes and a rim, the said rim engaging, at its outer periphery, the said combining device; and a connection of one point only, between the said members, connecting the said members relatively together.

4. In a wheel, the combination with a tire member comprising a tire-rim, and a tire supported directly thereby upon its outer periphery, of a combining device, comprising a resilient ring, supported directly against the inner periphery of the said tire-rim, an independent hub member comprising a hub, spokes and a rim, the said rim engaging, at its outer periphery, the said combining device; and a link connecting the said members together, substantially as set forth.

5. In a wheel, the combination with a tire member comprising a tire-rim, and a tire supported directly thereby upon its outer periphery, of a combining device, supported directly against the inner periphery of the said tire-rim, an independent hub member comprising a hub, spokes and a rim, the said rim engaging, at its outer periphery, the said combining device; and a link connecting the said members together, substantially as set forth.

6. In a wheel, the combination with a tire member comprising a hub, spokes and a rim, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, guide-plates secured to the said tire-rim and extending laterally over the said resilient ring and hub-rim, and bolts, arranged within the hub-rim and between the said spokes, for securing the inner ends of the said guide-plates together; and a connection between one of the spokes only and the said tire member.

7. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, guide-plates secured to the said tire-rim and extending laterally over the said resilient ring and hub-rim, and bolts, arranged within the hub-rim and between the said spokes, for securing the inner ends of the said guide-plates together; and a link connecting the said members together, substantially as set forth.

8. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, guide-plates secured to the said tire-rim and extending laterally over the said resilient ring and hub-rim, and bolts, arranged within the hub-rim and between the said spokes, for securing the inner ends of the said guide-plates together; and a link pivotally connected at one end to one of said spokes and at the other end to one of the said guide-plates securing-bolts, substantially as specified.

9. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, guide-plates, consisting each of a plurality of arms 7 secured to the said tire-rim, and a continuous ring 12 connected to said arms, the inner diameter of said rings 12 being less than the inner diameter of the said hub-rim, and bolts, arranged within the hub-rim and between the said spokes, for securing the said guide-plates together; and a connection between one of the spokes only and the said guide-plates.

10. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, guide-plates, consisting each of a plurality of arms 7 secured to the said tire-rim, and a continuous ring 12 connected to said arms, the inner diameter of said rings 12 being less than the inner diameter of the said hub-rim, and bolts, arranged within the hub-rim and between the said spokes, for securing the said guide-plates together; and a link pivotally connected at one of its ends to one of said spokes and at the other of its ends to said guide-plates.

11. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, the spokes provided at substantially their outer ends with laterally-projecting ears forming bearing-threads, of a combining device, comprising a resilient ring, engaged by the outer face of said rim,

11. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, the spokes provided at substantially their outer ends with laterally-projecting ears forming bearing-faces, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, guide-plates secured to the said tire-rim and projecting inwardly over the said resilient ring and hub-rim, and engaging the laterally-projecting ears or bearing-faces of said spokes, and bolts, arranged within the hub-rim and between the said spokes, for securing the inner ends of the said guide-plates together; and a connection at one point only, between the said members, connecting the said members relatively together.

12. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, the spokes provided at substantially their outer ends with laterally-projecting ears forming bearing-faces, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, guide-plates secured to the said tire-rim and projecting inwardly over the said resilient ring and hub-rim, and engaging the laterally-projecting ears or bearing-faces of said spokes, and bolts, arranged within the hub-rim and between the said spokes, for securing the inner ends of the said guide-plates together; and a link pivotally connected at one of its ends to said tire member and at the other of its ends to said hub member.

13. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, the inner periphery of which directly engages the said resilient ring, and guide-plates extending inwardly from said tire-rim and engaging said hub member laterally, said guide-plates also having portions laterally projecting therefrom to engage said hub member radially upon a two extended movement of one member with respect to the other; and a link connecting the said members together.

14. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, the spokes provided at substantially their outer ends with laterally-projecting ears forming bearing-faces, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, and guide-plates secured to the said tire-rim and projecting inwardly over the said resilient ring and hub-rim, and engaging the laterally-projecting ears or bearing-faces of said spokes, said guide-plates also having portions laterally projecting therefrom to engage the radial edges of said hub-member ears or bearing-faces, upon a two extended movement of one member with respect to the other; and a link connecting the said members together, substantially as set forth.

15. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, guide-plates secured to the said tire-rim and extending inwardly over the said resilient ring and hub-rim, said guide-plates having spring-pieces between them, and bolts, arranged within the hub-rim and between the said spokes, for securing the inner ends of the said guide-plates together; and a link connecting the said members together, substantially as set forth.

16. In a wheel, the combination with a hub member comprising a hub, spokes and a rim, of a combining device, comprising a resilient ring, engaged by the outer face of said rim, a tire member comprising a tire-rim, the inner periphery of which directly engages the said resilient ring, guide-plates secured to the said tire-rim and extending inwardly over the said resilient ring and hub-rim, said guide-plates having interlocking spring-pieces extending laterally between them, and bolts, arranged within the hub-rim and between the said spokes, for securing the inner ends of the said guide-plates together; and a link connecting the said members together, substantially as set forth.

700,490. TIRE-TIGHTENER. FRANK HERR, Goodenot, Kans. Filed Jan. 28, 1901. Serial No. 48,054. (No model.)

Claim.—A tire-tightener comprising metal sockets to receive the meeting ends of a wood felly and an oppositely-threaded bolt the opposite ends of which are seated in correspondingly-threaded apertures in the adjacent end walls of the sockets; said sockets being split and provided with transverse clamping-bolts.

700,491. SAFETY SPEED-LIMITING MEANS. GARNETT W. REBER, Indianapolis, Ind., assignor to Reber's Novelty Company, Indianapolis, Ind. Filed Oct. 14, 1901. Serial No. 73,547. (No model.)

Claim.—1. A mechanism including a driving-wheel, a driven wheel operated by means of the driving-wheel, a driven shaft, an isolating case attached to the driven shaft, and a controller located in the case and operatively connecting the driven wheel with the driven shaft, whereby the driven shaft may be actuated by the driven wheel and its rate of speed limited to a lesser proportional rate of that of the driven wheel.

2. A mechanism including a driving-wheel, a driven wheel operated by means of the driving-wheel, a driven shaft, an isolating case, a wedge member mounted on the shaft and having operative connection with the driven wheel, and a wedge member located in the case and adapted to contact with the wedge member, whereby the driven shaft may be actuated and the speed rate thereof limited to a fractional part of the speed to which the driven wheel may attain.

3. A mechanism including a driving-wheel, a driven shaft, a driven wheel, an isolating case, a wedge member mounted so as to move longitudinally on the driven shaft and operatively connected with the driven wheel, a wedge-block mounted in the isolating case and having sliding contact with the wedge member, and a spring pressed between the wedge-block and the rim of the isolating case, whereby the driven shaft may be actuated and its speed limited to a fractional part of the speed of the driven wheel.

4. A mechanism including a driving-wheel, a driven shaft, a driven wheel, a controller comprising a wedge member, a case having a flange extending substantially in the wedge member, wedge-blocks in the case, and springs in the case engaging the wedge-blocks, whereby the driven wheel may impart variable-speed motion to the driven shaft.

5. A mechanism including a driving-wheel, a driven shaft, a driven wheel operated by means of the driving-wheel, a spring operating so as to elastically hold the driven wheel against the periphery of the driven shaft, a wedge member movable on the driven shaft and operatively connecting with the driven wheel, wedge-blocks engaging with the wedge member, springs for the wedge-blocks, and a case including and supporting the wedge-blocks and the springs and attached to the driven shaft, whereby the velocity of the driven shaft may be limited to a predetermined rate relative to the rate of speed of the driven wheel.

6. A speed-limiting means including a driving-wheel, a driven shaft, a driven wheel operated by means of direct contact with the periphery of the driving-wheel and mounted revolvably on the driven shaft, a spring operating to elastically force the driven wheel constantly against the driving-wheel, a central wedge member operatively connected with the driven wheel, an isolating case attached to the driven shaft, and controlling mechanism mounted in the case and coacting with the central wedge member, whereby the driven shaft may be actuated at variable speeds by the driven wheel and the velocity of the driven shaft limited.

7. An electricity-generating machine comprising a main base, an armature-shaft, a driven pulley relative to the armature-shaft, an isolating case adjustably attached to the armature-shaft and provided with induced power-controlled mechanism whereby the driven pulley may be linked to the armature-shaft and speed-controlled means whereby the driven pulley may be released from connection with the armature-shaft, a driving-wheel in contact with the relative driven pulley, and a cushion for absorbing the thrust imparted by the driven wheel to the driven pulley.

8. In an electricity-generating machine, a fixed main base, a movable base upon the main base, journal-bearings supported by the movable base, a generator-shaft mounted rotatively in said bearings, the spring acting against the movable base, a driven wheel mounted rotatively on the generator-shaft, a driving-wheel in constant contact with the driven wheel, and automatically-controlled mechanism whereby the driven wheel is caused to have intermittent operative contact with the generator-shaft, in combination with a gas-engine and clutch-rod connecting the gas-engine with the generating-machine.

9. In an electricity-generating machine, the combination with a driving-wheel and a driven shaft, of a driven wheel relative to the driven shaft and operated by means of the driving-wheel, a supporting-case adjustably secured to the driven shaft, a controller in the case and coacting therewith and also with the driven wheel, whereby the driven shaft may be actuated and the speed rate thereof limited to a fractional part of the speed to which the driven wheel may attain.

10. In an electricity-generating machine, the combination with a gas-engine having a relative wheel, of a generator-shaft provided with a sleeve movable longitudinally on the shaft and having a frictional contact-face, a driven wheel mounted rotatively on the generator-shaft and having variably-framed contact with the frictional contact-face of the sleeve-shaft, and also having constant contact with the relative wheel of the gas-engine, and means whereby the force of the contact between the movable sleeve and the driven wheel may be automatically graduated.

11. In an electricity-generating machine, the combination with a driving-wheel, a driven wheel having a frictional contact-face, a generator-shaft, means for generating and conducting a current, a gas-engine having a relative wheel in constant operative connection with the driven wheel, and a controlling mechanism, of a movable connector having a frictional contact-face adapted to engage the contact-face of the driven wheel and partially support the driven wheel in operative connection with the controlling mechanism, whereby the driven wheel may impart variable rates of speed to the generator-shaft.

12. In an electricity-generating machine, means for generating and conducting an electric current, a driven shaft, a driven wheel, a relatively fixed bearing at one side of the driven wheel, a relatively movable bearing at the opposite side of the driven wheel, in combination with an automatically-operated controller coacting with the movable bearing, whereby the driven wheel may be caused to have intermittent operative connection with the driven shaft, and a driving-wheel having operative connection with the driven wheel.

13. In an electricity-generating machine, the combination with a driving-wheel, of a base, a driven shaft supported by means of the base, a driven wheel relative to the driven shaft and driven by means of the driving-wheel, a supporting-case adjustably secured to the driven shaft, a controller supported in the case and coacting therewith and also with the driven wheel whereby the driven shaft may be actuated and its velocity limited to a lesser rate than that of the driven wheel, and a cushion interposed operatively between the driving-wheel and the base whereby the thrust of the driving-wheel against the generating-machine may be absorbed.

14. In an electricity-generating machine, the combination of a main base, journal-bearings supported substantially by the base, a generator-shaft mounted rotatively in the bearings, a driven wheel having a plurality of friction-faces and mounted rotatively on the generator-shaft, friction members having operative connection with the generator-shaft and also with one of the plurality of friction-faces, automatically-controlled mechanism whereby the friction members may be caused to have intermittent operative contact with the friction-faces, whereby the driven wheel may impart variable rates of speed to the generator-shaft, in combination with a gas-engine, having a driving-wheel in operative connection with one of the plurality of friction-faces, and clutch-rod connecting the gas-engine with the generating-machine.

15. In an electricity-generating machine, a driven shaft, an isolating case attached to the driven shaft, a driven wheel mounted rotatively on the driven shaft, a movable locking device adapted to engage the driven pulley, and a controller mechanism operating against the locking device and also within the case and against the front and the flange or rim thereof, in combination with means for generating and conducting an electric current, and a gas-engine having a relative wheel in operative connection with the driven wheel.

16. In an electricity-generating machine, the combination of a driven shaft, a driven wheel relative to the driven shaft, means connected with the driven shaft whereby electricity may be generated, a sleeve mounted so as to move longitudinally on the driven shaft and having a friction-face in operative connection with the driven wheel, means whereby the sleeve may be automatically moved to and from the driven wheel and having a supporting member adjustably secured to the driven shaft, whereby the driven wheel may impart variable-speed motion to the driven shaft, in combination with a gas-engine, clutch-rod connecting the gas-engine with the generating-machine, and a driving-wheel connected operatively to the driven wheel.

17. In an electricity-generating machine, the combination of a driving-wheel, a driven shaft, a driven wheel relative to the driven shaft and having an elastic rim in contact with the periphery of the driving-wheel, a sleeve movable longitudinally on the driven shaft and rotatively thereon and having a friction-face in operative connection with the driven wheel, a supporting member secured to the driven shaft, automatically-operated means carried by the supporting member and operatively connected with the sleeve, whereby the driven shaft may be actuated by the driven wheel and the thrust thereof absorbed, and the velocity of the driven shaft limited to a predetermined rate relative to the peripheral speed of the driving-wheel, with a gas-engine actuating the driven wheel, and clutch-rod connecting the gas-engine with the generating-machine.

18. In an electricity-generating machine, a driving-wheel, a driven shaft, a driven wheel relative to the driven shaft and having the periph-

ery thereof in contact with the periphery of the driving-wheel, a supporting member secured to the driven shaft, and movable members having frictional contact-faces normally connecting the driven wheel to the supporting member whereby the driven wheel may rotate the driven shaft and whereby the driven wheel may be disconnected from the driven shaft, in combination with a gas-engine actuating the driving-wheel, and clutch-rod connecting the gas-engine with the generating-machine.

19. In an electricity-generating machine, the combination of a driven shaft, means for generating electricity connected with the driven shaft, a driven wheel relative to the driven shaft and having a frictional contact-face, a controlling mechanism, and a movable connector having a frictional contact-face adapted to engage the contact-face of the driven wheel in operative connection with the controlling mechanism, whereby the driven wheel may impart variable rates of speed to the driven shaft, with a gas-engine, a driving-wheel actuated by the gas-engine and connected with the driven wheel, and clutch-rod connecting the gas-engine with the means for generating electricity.

20. In an electricity-generating machine, the combination of the main base, the generator-shaft, the generator connected with the generator-shaft, the driven wheel relative to the generator-shaft, the groove in the periphery of said wheel, the supporting member secured to the generator-shaft, and the controller mechanism operatively connecting the supporting member with said driven wheel, with the gas-engine, the driving-wheel operatively connected with said driven wheel, and the clutch-rod connecting the gas-engine with the generator.

21. In an electricity-generating machine, the combination of the generator-shaft, the generator connected with said shaft, the supplemental extension-shaft having the socket connected detachably to said generator-shaft, the driven wheel relative to said extension-shaft, the supporting member secured to said extension-shaft, the movable connector and the controller connected with the supporting member and adapted to engage the movable connector, with the gas-engine, the driving-wheel actuating the driven wheel, and the clutch-rod connecting the gas-engine with the generator.

700,492. PEDAL FOR VEHICLES. EDWARD W. REBER, Chester, England. Filed July 17, 1902. Serial No. 28,924. (No model.)

Claim.—1. The combination, with a crank and a pedal-shaft provided to the outer end of the crank, said crank having a longitudinal slot in its outer end and a second longitudinal slot at an angle to the first and in the plane of movement of the pedal-shaft, of a wing projecting from said pedal-shaft and entering the said second slot, a slot in said wing registering with the first slot of the crank when the shaft is in lowered position, a locking-bar pivoted at one end to one side of the crank and adapted to swing in the first slot across the second, a screw-threaded projection on the opposite end of the locking-bar, and means for connecting said projection with the crank, substantially as set forth.

2. The combination, with a crank and a pedal-shaft pivoted to the outer end of the crank, said crank having a longitudinal slot in its outer end and a second longitudinal slot at an angle to the first and in the plane of movement of the pedal-shaft, of a wing projecting from said pedal-shaft and entering said second slot, a slot in said wing registering with the first slot of the crank when the shaft is in lowered position, a locking-bar pivoted at one end to one side of the crank and adapted to swing in the first slot across the second, a screw-threaded projection on the opposite end of the locking-bar and projecting beyond the side of the crank, and a locking-out on said projection, substantially as set forth.

700,493. GRADING APPARATUS. GEORGE A. REBER, the Franchise, Cal. Filed Mar. 12, 1902. Serial No. 57,955. (Model.)

Claim.—1. In a machine for leveling road-surfaces, the combination with the traveling roller for receiving a design from one board and transferring it to another, of a blinding-brush mounted so as to follow the said roller in its transferring operation.

2. In a machine for leveling road-surfaces the combination of a base, a traveling structure mounted thereon, a roller suspended and revolvable in said structure and an adjustable blinding-brush also mounted in said traveling structure.

3. In a machine for leveling road-surfaces, the combination of a base, a traveling structure mounted thereon, a roller-frame vertically movable in said traveling structure and carrying a roller, a spreader hinged to the traveling structure and a scraper also hinged thereto.

4. In a machine for imitating wood-grain, the combination of a base, a traveling structure mounted thereon, a roller-frame vertically movable in said traveling structure and carrying a roller, a spreader hinged to the traveling structure, a scraper also hinged thereto and a blinding-brush.

5. In a machine for imitating wood-grain, a trough-like base having guides, and provided with means for supporting two boards simultaneously and upon substantially the same plane, a frame, a structure movable in said guides, and an adjustable roller, an adjustable spreader and an adjustable scraper all carried by said movable structure.

700,494. ELECTRIC HEATER. WALTER R. HERRMAN, Joplin, Mo., assignor of one-half to Edward R. Harris, Joplin, Mo. Filed Feb. 11, 1901. Serial No. 44,929. (No model.)

Claim.—A heater comprising a tapered shell or casing consisting of a body and a cover, each provided in its side with openings for the circulation of air, the meeting edges of one end of the body and of the cover being each provided with a recess, the two forming an opening, a bed of loose filamentous material inclosed by the casing and through which air is free to circulate, an incandescent electric lamp nested in the said material and having its stem seated in the opening formed by the registering recesses of the body and cover, and projecting beyond the end of the casing, and spring fastening means for holding the body and cover assembled, substantially as described.

700,495. ELECTRODES FOR ARC-LAMPS. ROBERT HARTER, Berlin, Germany. Filed Feb. 24, 1902. Serial No. 28,414. (No model.)

Claim.—1. As a new article of manufacture an arc-lamp electrode of carbide, having a covering-envelope impervious to water to protect the electrode against the decomposing action of the moisture of the air.

2. As a new article of manufacture, an arc-lamp electrode of carbide having a solid metal envelope protecting the carbide from moisture, substantially as described.

3. As a new article of manufacture an arc-lamp carbide electrode having a protective envelope of aluminum.

700,496. ELECTRIC FIRE-ALARM. CONRAD HENKE, New York, N. Y. Filed Sept. 3, 1900. Serial No. 24,609. (No model.)

Claim.—1. The combination with a clock having an alarm-train, of a lamp and battery, two circuits in series therewith and in circuit with each other, a spring-arm, adjacent to the driving-spring of the alarm-train, a fixed contact-point with which the spring-arm makes contact upon the unwinding of the driving-spring, a manually-controlled contact, the arm, post and manually-controlled contact being located in one of the

aid circuit-circuit, and a manually-controlled contact located in the other circuit-circuit, substantially as described.

2. The combination with a clock having an alarm-train, of a battery and a lamp, a spring-arm adjacent to the driving-spring of the alarm-train, a fixed contact-point with which the spring makes contact upon the unwinding of the driving-spring, and a manually-controlled contact, the battery, lamp, arm, post and manually-controlled contact being in the same circuit, substantially as described.

3. The combination with a clock, of a hollow base therefor, a series of battery elements contained in the base, an electric lamp located upon the base, and having its one terminal connected to one terminal of the battery, a switch-point located upon the base connected to the opposite terminal of the lamp, two contact-points with which the switch-point makes contact and connected to the opposite terminal of the battery, a spring-arm and a contact-post connected between one of the contact-points and the said last-named terminal of the lamp, and an alarm-train having a driving-spring, released by the clock for bringing the spring-arm and the post into contact, substantially as described.

4. The combination with a clock and a hollow base therefor, of a framing forming a series of compartments, contained in the base, a clock, a lamp, a switch-point and two contact-points all mounted on the base, a spring-actuated alarm-train contained in the clock and released by the time-train thereof, two contact-points located at the same end of each compartment, a battery-cell contained in each compartment and having the elements thereof in contact with the contact-points in that compartment, a spring contact-arm and contact-post therefor adjacent to each other and to the driving-spring of the alarm-train, and conductors passing between the top of the base and the top of the casing and connecting a contact in one of the compartments with one of the contact-points upon the base and with the spring-arm, connecting the opposite point upon the base with the contact-post, and connecting, through the lamp, a contact-point in one of the compartments with the switch-point, substantially as described.

700,497. ELECTRIC BATTERY. CONRAD HENKE, New York, N. Y. Original application filed Aug. 9, 1900. Serial No. 24,597. Revised and this application filed Apr. 1, 1901. Serial No. 28,380. (No model.)

Claim.—1. As a new and improved article of manufacture the heretofore-described battery-cell having two elements, and having a centrally-disposed contact-point and a surrounding annulus upon one end thereof, substantially flush with each other and connected respectively with the several elements, the contact-point and annulus forming terminals of the respective elements of the cell, substantially as described.

2. As a new and improved article of manufacture, the heretofore-described battery-cell consisting of two elements, one element being centrally located and the other element surrounding the first-named element and being concentric therewith, and a button and a surrounding annulus, substantially flush with each other, and connected to the central and concentric elements respectively, substantially as described.

3. As a new and improved article of manufacture, the heretofore-described battery-cell, consisting of a cup-shaped cell forming one element

of the battery and inclosing another element centrally located therein, the open end of the cell being closed by a coating of insulating material separating the said element, the cell being surrounded by an annulus electrically connected to the other element, and a button upon the upper end of the centrally-located element, the button being substantially flush with the annulus, from which it is separated, substantially as described.

4. The heretofore-described battery-cell having two elements, and having upon one end thereof a centrally-disposed point and a surrounding annulus, substantially as described, connected respectively to the several elements of the cell, the point and annulus forming terminals of the respective elements of the cell and being adapted to bear upon terminals of an external circuit, and to electrically connect the elements of the cell therewith, as and for the purpose set forth.

5. As a new and improved article of manufacture, the heretofore-described battery-cell with positive and negative elements, having a centrally-disposed contact-point and a surrounding contact-plate upon one end thereof, the surrounding contact-plate being formed by an annulus, the central point and the surrounding annulus being connected one to the positive and the other to the negative element of the cell, and forming terminals of the said elements, substantially as described.

700,498. GARMENT-SUPPORTER. WILLIAM S. BUCKNER, Meriden Park, Mass. Original application filed Dec. 26, 1901. Serial No. 27,542. Revised and this application filed Apr. 4, 1902. Serial No. 28,428. (No model.)

Claim.—1. As an article of manufacture, a garment-supporter comprising shoulder-straps, a band adapted to encircle the wearer, a button for connecting said shoulder-straps and said band, an extension for said button to the outside of said band to which outside garments may be attached, substantially as described.

2. As an article of manufacture, a garment-supporter comprising shoulder-straps, a band adapted to encircle the wearer, a button for said shoulder-straps and said band, and means of connection for the outside of said band adjacent said button adapted to connect with a loop by which the outer garments may be attached, substantially as described.

3. As an article of manufacture, the combination of a band adapted to encircle the waist of a wearer, a button secured to said band adapted to connect with a suspender-loop, a clasp projection from said band adjacent said button and a buttonhole-loop extending with said clasp and adapted to be attached to a button, substantially as described.

700,499. BOTTLE-CLEANER. DAVID E. IRVIN, Boston, Mass., assignor of one-half to Jonathan Chase, Boston, Mass. Filed Aug. 2, 1901. Serial No. 78,041. (No model.)

Claim.—1. A bottle-washer comprising a stopper and a looped or doubled chain attached to the said stopper.

2. A bottle-washer comprising a stopper, a wire passing therethrough, and a looped or doubled chain attached to the said wire, the wire being secured from retraction by having the upper portion thereof bent to form a handhold.

700,500. STEAK-THENDER. WARREN W. JACOBUS, Little Canada, N. Y. Filed Jan. 29, 1902. Serial No. 31,794. (No model.)

Claim.—1. A device of the class described consisting of a base and uprights formed integral, said uprights having vertical slots having end bearing-surfaces, a roller disposed between the uprights and having transverse engagement with the upper bearing-surfaces, one slot having its lower portion enlarged to permit of passage of the roller therethrough and a second roller having a crank formed integral therewith, said roller having a transverse slot at one end and engaged with the lower end of one slot and having an enlarged bearing at its opposite end engaged with the enlargement of the other slot.

2. A device of the class described comprising spaced uprights having longitudinal slots having end bearings, the bearing at one end of the slot being enlarged and grooved circumferentially, corrugated roller having transverse engagement with the upper bearing of the slot, and a second roller having an enlarged bearing at one end and curved in cross-section and engaged in the grooved bearing and having a transverse slot at its opposite end engaged with the other slot, the second roller being corrugated and having a crank for rotating it.

700,501. APARTMENT-HOUSE. WILLIAM C. JAMES, Chicago, Ill. Filed June 17, 1901. Serial No. 24,947. (No model.)

Claim.—1. A compartment-section for a house comprising a case divided by partitions to form at one end a toilet-compartment, at the other end a nursery and clothes and coat storage closet; and between the toilet-compartment and the closet, a bed-holding compartment, and a kitchen and pantry compartment; a bath-tub of greater length than the depth of the toilet-compartment, mounted in said toilet-compartment to slide out and in; a combined clothes-rack and coat-hanger interchangeably mounted in the closet end and on the top of the outboard bath-tub for interchangeability as a clothes-rack and tub; a bed pivoted in the bed-holding compartment; an upright curtain mounted in the compartment-section, to be drawn out to form a partition in any apartment of which the face of the compartment-section forms a side, to divide each apartment into two

rooms, one of which rooms is thereby adapted for a bed-room, living-room and back parlor, while the other room is adapted for a toilet, bathroom and bed-room.

2. A compartment-eccles for a house, comprising a case divided by partitions to form at one end a toilet-compartment, at the other end a secretary and clothes and coat storage closet, and between the toilet-compartment and the closet, a bed-holding compartment and a kitchen and pantry compartment; a bath-tub of greater length than the depth of the toilet-compartment mounted in said toilet-compartment to slide out and in; a combined clothes-rack and coat-hum interchangably mounted in the closet and on the top of the outdrawn bath-tub for interchangable use as a clothes-rack and coat-hum; a bed pivoted to fold into the bed-holding compartment and furnished with a shelf to form a bed when the case is lowered, the bottom of said bed being formed to close the front of the bed-holding compartment and to imitate a fireplace; a door to close the kitchen-compartment; and an upright curtain mounted in the kitchen-compartment to be drawn out through an opening in said compartment-eccles to form a partition in any apartment of which the face of the compartment-eccles forms a side.

3. A compartment-eccles for a house, comprising a case divided by partitions to form at one end a toilet-compartment and at the other end a closet; a secretary forming a door for the closet; a bed-holding compartment next to the closet; a bed pivoted to fold into the bed-holding compartment and to form an ornamental closure for the front of said compartment; a kitchen-compartment; a bath-tub of greater length than the depth of the toilet-compartment, mounted in said toilet-compartment to slide out and in; a portable window-seat furnished with a chamber to receive the projecting end of the bath-tub when the bath-tub is slid into the toilet-compartment, said window-seat being formed next to the kitchen-compartment in an oblique head; a door to close the kitchen-compartment and formed in two leaves hinged together, one of said leaves being of the width of one side of said head, and the other leaf hinged to the edge of said first-named leaf; a stove fastened to said first-named leaf to be swung into and out of the kitchen-compartment; and an upright curtain mounted in the kitchen-compartment and adapted to be outdrawn to form a partition in any apartment of which the face of the compartment-eccles forms a side.

4. A compartment-eccles for a house, comprising a case divided by partitions to form at one end a toilet-compartment and at another end a bed-holding compartment; a bed pivoted to fold into the bed-holding compartment; toilet appliances to slide into the toilet-compartment; and an upright curtain mounted in said compartment-eccles, to be outdrawn therefrom to form a partition between the toilet and the bed in any apartment of which the face of the compartment-eccles forms a side.

5. A compartment-eccles for a house, comprising a case divided by partitions to form at one end a bed-holding compartment and at another end a kitchen-compartment; a bed pivoted to fold into the bed-holding compartment and to form an ornamental closure therefor; a door to close the opening into the kitchen-compartment; and an upright curtain mounted in the compartment-eccles to be outdrawn therefrom to form a partition between the bed and the kitchen-compartment in any apartment of which the face of the compartment-eccles forms a side.

6. A compartment-eccles for a house, comprising a case divided by partitions to form a bed-holding compartment and a kitchen-compartment adjacent to each other; a ventilating-well behind the bed-holding compartment, divided into two upright air-passages; an opening leading into one of said passages from the kitchen-compartment, said passages being close to the bed-holding compartment, an opening being provided between the bed-holding compartment and the other air-passage; means for closing said last-named opening; and a bed pivoted to fold into the bed-holding compartment to form an ornamental closure for said compartment.

7. A compartment-eccles for a house, comprising a case divided by partitions to form a bed-holding compartment and a closet-compartment adjacent thereto; a ventilating-well behind the bed-holding compartment; openings being provided between the ventilating-well and the bed-holding compartment and closet respectively; means for closing said openings; a door for the closet; and a bed pivoted to fold into the bed-holding compartment to form a closure for the same.

8. An apartment-house comprising walls to form one or more pairs of double apartments, the double apartments of each pair being furnished respectively at one end with a compartment-eccles, the apartments of each pair of double apartments being arranged with their compartment-eccles abutting; plumbing connections between the abutting compartment-eccles; and plumbing-fittings in said compartment-eccles respectively and connected with said plumbing connections.

9. An apartment-house comprising walls to form a double apartment and furnished at one end with a main partition to cut off a compartment-eccles at that end of said double apartment; a plurality of sub-partitions extending from said main partition to the end wall of the com-

partment to form with said partition and the walls of the compartment-eccles cut off by said partition, a closet, a bed-holder, a pantry and kitchen, and a bath-tub and washstand holder; a bath-tub and a wash-bowl and fixtures in said bath-tub and bed-holder and the bath-tub and washstand holder to extend across the apartment, substantially as and for the purposes set forth.

10. A house, comprising the walls of an apartment, a cross-partition and subpartitions at one end of said apartment to form a closet and bed-storing compartment, a bed-holder, a kitchen and pantry compartment, and a toilet-compartment; a bed pivoted in the bed-holder and having its under side formed with a shelf projection to constitute a support for the bed when the bed is down, and a shelf when the bed is folded up into the holder; a ventilating-well being formed between the bed-holder and the end wall of the apartment; a vertical partition dividing said well into two upright passages; valved openings being provided between one of said passages and the closet-compartment and the bed-holder respectively; a valved opening being provided between the other side and the kitchen and pantry compartment; a door for the closet formed in a secretary; a door for the kitchen-compartment; a bath-tub for the bath-tub holder; an upright spring-controlled curtain at the compartment-forming partition; and means for fastening the free end of said curtain in upright position at the opposite wall of the apartment.

11. An apartment-house comprising walls to form an apartment; a cross-partition and subpartitions at one end of said apartment to form a closet and bed-storing compartment, a bed-holder, a kitchen and a pantry compartment, and a toilet-compartment; a bed pivoted in the bed-holder and having its under side formed with a shelf projection to constitute a support for the bed when the bed is down and a shelf when the bed is folded into the holder; a ventilating-well being formed between the bed-holder and the end wall of the apartment; a vertical partition dividing said well into two upright passages, valved openings being provided between one of said passages and the closet-compartment and the bed-holder respectively; means in the upright passage which communicates with the closet-compartment for holding clothes for drying; perforated shelves in the other passage which communicates with the kitchen-compartment; a swinging bracket mounted to swing into and out of the well front and into the kitchen-compartment; a bath-tub mounted to slide into and out of the toilet-compartment; a cut-draw capable of being stored in the closet-compartment and adapted to be applied to the top of the bath-tub when drawn out and furnished at one end with a folding leg to rest upon the floor to support the foot of the cut-bed, said cut-bed being furnished on its under side with legs for supporting clothes of the cut-bed to air the same when in the closet.

12. In an apartment-house, a double apartment furnished at one side with a partition forming a number of compartments; a curtain to temporarily separate one of the apartments into two rooms; a bed-holder and bed being in one of said rooms; a movable bath-tub in the other of said rooms adapted to move into and out of one of the compartments of the end of said room; plumbing appliances to receive the discharge from the bath-tub and to allow the bath-tub to move freely; and a seat to sit over the outer end of said bath-tub to conceal the same.

13. In an apartment-house, a row of compartments, one of said compartments being arranged to receive a movable bath-tub and another of said compartments being provided with a receptacle for a cut-bed frame; a bath-tub in the bath-tub compartment and the cut-bed frame interchangably adapted for the cut-bed-frame compartment and for the bath-tub, said frame being adapted to fit upon the bath-tub when the same is drawn out from its compartment.

14. An apartment-house furnished with walls to form an apartment and at one end of said apartment, partitions and subpartitions to form a plurality of compartments, one of said compartments forming a bed-holder and bed-holding compartment, an air-passage; a valved opening between the bed-holder compartment and the air-passage; and a bed-frame fitting in the bed-holder and having its bottom formed in an imitation mantelpiece, the shelf of which is adapted to form a support for the bed when the same is lowered into position for use; the bottom of said bed forming a closure for the said opening.

15. An apartment-house furnished at one end of one of its apartments with a bath-tub-holding compartment; a bath-tub to slide into and out of said compartment and being of greater length than the chamber of the compartment; a sliding case furnished with a wash-bowl and sliding into said compartment above the bath-tub; water-applying fixtures in the wall of the bath-tub compartment above the sliding case; a chair formed with a chamber beneath to rest closed at front and side to chamber the protruding end of the bath-tub; and having a back hinged to said case and arranged to stand up to conceal the drawer and water-fixture, and to fold down upon the bath-tub to allow the case to be slid out.

16. In an apartment-house, a compartment-eccles furnished with a kitchen-compartment and a ventilating-well; a door for the ventilating-

well; a swinging bracket on said door; and a water-holder on said swinging bracket.

17. In an apartment-house, a compartment-eccles furnished with a ventilating-well and a bed-holder compartment in front of said well; a door communicating between the bed-holding compartment and the well; and a bed pivoted in said bed-holder to fold up and close the opening thereof.

18. In an apartment-house, a bed-holding compartment having an extension below the level of the floor of the compartment; and a bed pivoted in said compartment to extend into said room when brought into upright position.

19. The combination with the apartment-floor and the bed-holding compartment extending above and below said floor, of a bed pivoted to swing into and out of said compartment and furnished in its bottom with a recess to receive the edge of the floor to cover the joint between the floor and the bed when the bed is in upright position.

20. In an apartment-house, a bath-tub-receiving compartment; a trough below said compartment; a trap and cover communicating leading from said trough; and a bath-tub to slide in said compartment above said trough and furnished with a discharge-pipe to discharge into said trough.

21. In an apartment-house, a ventilating-well furnished with funnel-shaped shelves, substantially as and for the purposes set forth.

22. In an apartment-house, a compartment-eccles forming one end of an apartment and provided with a kitchen-compartment and a double-headed door for closing said compartment, and a stove fastened to the cabinet of said door to be swung into and out of the kitchen-compartment.

23. In an apartment-house, a door closing one of the compartments and furnished on its inner side with a removable panel and a table with a hinged top of smaller size than the removable panel of the door, and means for connecting the table-top and the door-panel to thereby form a table of larger dimensions.

24. A door furnished with a panel-holder; a removable panel in said holder furnished with a back; means for retaining said panel in said panel-holder; a table furnished with a hinged top of smaller dimensions than the panel, and also furnished with means to receive the back of the panel; the several parts being constructed and arranged to bring said table below said back to receive the same when the table-top is tilted and to lift the panel from the holder when the table-top is brought to horizontal position.

25. The combination of an upright panel-holder; a panel for said holder; a table furnished with a hinged top; and an attachment for connecting said hinged top with the panel to lift the same from the holder, substantially as set forth.

26. The combination of a panel-holder; a panel for said holder; a stand; and an attachment for connecting the top of the stand with the panel to lift the same from the holder.

700,502. SEAL-LOCK. HENRY T. JONES, Long Island, Queens County, N. Y. Filed July 25, 1904. Serial No. 69,692. (No model.)

Claim.—1. A device of the class described comprising a hoop provided with a head having an opening, a tubular staple-bolt provided with a head adapted to pass through said opening and having a vertically-arranged eye or passage formed therein, a frangible seal comprising a head portion and a shank, the latter being adapted to pass through said eye or passage and a spring-operated latch-bolt mounted in said staple-bolt and adapted to engage the shank of the seal, and a securing-pin connected with the hoop and adapted to be passed through the head of the staple-bolt, substantially as shown and described.

2. A device of the class specified comprising a hoop provided with a head having an opening, a tubular staple-bolt provided with a head adapted to pass through said opening and having a vertically-arranged eye or passage formed therein, a frangible seal comprising a head portion and a shank, the latter being adapted to pass through said eye or passage and a spring-operated latch-bolt mounted in said staple-bolt and adapted to engage the shank of the seal, the shank of the seal being also provided with a triangular notch or recess and the head of the latch-bolt being beveled on the upper side thereof, substantially as shown and described.

700,503. PLASTER AND GROUTING. JAMES R. JONES, Jackson, Miss. Original application filed May 7, 1901, Serial No. 69,128. Divided and this application filed Sept. 13, 1904. Serial No. 70,577. (No model.)

Claim.—1. Is a plaster, a hopper, a seed-conducting tube or boot, a valve within the said tube or boot having a section extending out therefrom, and a wheel mounted to revolve in the hopper, provided with projections adapted to engage with the projecting portion of the valve, whereby the said valve is operated by the said wheel and the valve brought in position to temporarily hold the seed in the said tube and dump the same at the proper moment, as described.

2. In plaster and the machines, a frame, a receptacle located upon said frame, said receptacle being provided with a partition forming chamber therein, an outlet for the larger chamber, which chamber is adapted to receive a fertilizing material, a distributing-wheel provided with pockets mounted to revolve in the outlet portion of said larger chamber, a portion of the periphery of the wheel extending beyond said outlet, a finger secured to a wall of each of the said pockets, a seed-distributing tube, and a retaining-valve located within the said seed-distributing tube and operated by the fingers located in the pockets of the fertilizer-distributing wheel, as set forth.

700,504. LIGHTER. THOMAS W. JONES, Brooklyn, N. Y. Filed Jan. 7, 1905. Serial No. 69,725. (No model.)

Claim.—1. In combination, a ceiling-booth, a registering device located at a distance therefrom and consisting of a slotted table, a series of registering-wheels, an actuating-lever connected to said wheels and having its forward end terminating under the slot in the table, and means for normally pressing said lever toward said slot, and a chain connecting said registering device with the booth and having its receiving and terminating end close to the forward end of said lever, the lower edge of the chain terminating directly under the slot and the upper wall of the chain terminating short of the slot and being bulged upward at 14, whereby the return of said lever after each registering action will inject the chain but registered into the tube and back to the ceiling-booth.

2. In an apparatus of the class described, the combination of a registering apparatus, a check-calling booth, a check-receiving hopper arranged at a distance therefrom, a retaining-chain for returning the checks from the receiver to the ceiling-booth, and means at the register for positively impelling each check after it is received through said chain to the ceiling-booth.

3. In combination, a ceiling-booth, a check-receiving and registering device located at a distance from said booth, a chain connecting the registering device with the booth, and a check-impelling device connected

to the registering device and adapted to positively impel each sheet through the chute back to the booth after it is registered.

4. In combination with a sheet-calling booth, a sheet-registering device located at a distance therefrom, a connecting-chute arranged substantially horizontal, a lever adapted to be actuated by the sheet in the act of registering, said lever being arranged substantially in line with the receiving end of said chute and close thereto, and means for normally returning said lever after it is moved by the sheet, said action serving to inject the sheet into the chute and back to the booth.

5. In combination, a sheet-calling booth, a registering device located at a distance therefrom and consisting of a sheet table, a series of registering-wheels, an actuating-lever connected to said wheels and having its forward beveled end terminating under the slot in the table, means for normally pressing said lever toward said slot, a chute connecting said registering device with the booth and having its receiving end terminating under the slot in the table and close to the beveled nose of said lever, whereby the return of said lever after each registering action will inject the sheet into the chute and return it to the sheet-calling booth.

700,505. PAPER-FOLDING MACHINE. HOWARD E. KIM, Philadelphia, Pa., assignor to the CHAMBERLAIN BROTHERS COMPANY, Philadelphia, Pa., a Corporation of Pennsylvania. Filed Aug. 7, 1898. Serial No. 720,463. (No model.)

Claim.—1. In a folding-machine, the combination with the main frame, a set of horizontal folding-rollers therein, and means for rotating said rollers, of a frame adjustable toward and from said rollers, horizontal folding-rollers mounted in said frame, a set of inclined rollers also mounted in said frame, means for concurrently actuating said horizontal and inclined rollers, carrying-tapes leading from the first-named set of horizontal rollers to the second set, guide-rollers for said tapes on the adjustable frame, carrying-tapes extending from the latter set of rollers adjacent to and parallel with the inclined folding-rollers, guide-rollers for said latter tapes on the said adjustable frame, and means for bodily adjusting said frame, substantially as described.

2. In a folding-machine, the combination with the inclined folding-rollers and their supporting and operating parts, of a guide or supporting plate above and adjacent to said rollers, means whereby a previously-folded sheet is fed onto said plate, a stop or abutment bar on said plate, a push-rod, means whereby it is caused to act against the edge of the sheet to adjust the same, and means whereby the sheet is delivered to the said rollers and folded thereby, together with means for adjusting said stop-bar and push-rod in a direction parallel with the movement of the incoming sheet, substantially as described.

3. In a folding-machine, the combination with the final folding-rollers and their supporting and operating parts, of a guide-plate supported above and adjacent to said rollers, means whereby a previously-folded sheet is fed onto said plate, a side stop-bar for said sheet, a frictional de-

vice adjacent to said bar adapted to act on the upper edge of the sheet, a push device adapted to act upon the edge of the sheet and push the same to a prescribed position of adjustment, and means whereby the sheet is delivered to said rollers and folded thereby, substantially as described.

4. In a folding-machine, the combination with the final folding-rollers, and their supporting and operating parts, of a guide-plate supported above and adjacent to said rollers, means whereby a previously-folded sheet is fed onto said plate, a stop-bar, a frame on which it is pivotally mounted, means whereby said bar may be fixed in positions of lateral adjustment, a push bar adapted to slide upon said plate and act against the edge of the sheet, mechanism supported by said frame for reciprocating said bar, a support for said frame, means for bodily adjusting the latter, and means for actuating said reciprocating mechanism, together with means whereby the sheet is delivered to said rollers and folded thereby, substantially as described.

5. In a folding-machine, the combination with the final folding-rollers and their supporting and operating parts, of two parallel guides or supports arranged above and adjacent to said rollers, means whereby previously-folded sheets are fed onto the respective guides, a common stop-bar for the sheets on said guides or supports, the block provided with dovetail grooves, the push-rod whose outer ends are provided with dovetail engaging said grooves, the legs on said rods, the thumb-screws passing through said legs and into said block for adjusting the relative positions of said push-rods to said block, means for reciprocating said block and rods to adjust the sheet laterally upon said guides, and means whereby said sheets are delivered to the said rollers and folded thereby, substantially as described.

6. In a folding-machine, the combination with the final folding-rollers, and their supporting and operating parts, of two parallel guides or supports arranged above and adjacent to said rollers, means whereby previously-folded sheets are fed onto the respective guides, a common stop-bar for the sheets on said guides or supports provided with laterally-projecting flanges or projections against which the upper surfaces of the sheets on said guides are adapted to impinge, and push-rods movable upon the respective guides or supports and adjacent to said flanges or projections, and means whereby said sheets are delivered to said rollers and folded thereby, substantially as described.

7. In a folding-machine, the combination with the main frame, of a frame adjustably mounted thereon, the final folding-rollers mounted at an angle or inclination on said latter frame, means for operating said rollers, means whereby previously-folded sheets are fed above said rollers, means whereby said sheets are delivered between said rollers and folded thereby, a vertically-adjustable packing-trough mounted on said frame below and adjacent to said rollers and adapted to receive the finally-folded sheets, means for horizontally adjusting said frame, and means for vertically adjusting said trough, substantially as described.

8. In a folding-machine, the combination with the main frame, of a frame adjustably mounted thereon, the final folding-rollers mounted at an angle or inclination on said latter frame, means for operating said rollers, means whereby previously-folded sheets are fed above said rollers, means on said adjustable frame for sideways and adjusting the sheets in respect to the rollers, means whereby said sheets are delivered between said rollers and folded thereby, a vertically-adjustable packing-trough mounted on said frame below and adjacent to said rollers and adapted to receive the finally-folded sheets, means for horizontally adjusting said frame, and means for vertically adjusting said trough, substantially as described.

700,506. SHEET FOR SERIAL WINDOWS. ARTHUR O. KITTREDGE and ROBERT B. KITTREDGE, Jersey, N. J., assignors to the Account, Audit & Assessment Company, Limited, New York, N. Y., a Corporation of New Jersey. Filed Aug. 8, 1898. Serial No. 727,714. (No model.)

Claim.—1. As a new article of manufacture, the loose sheet for a serial binder having one edge thickened to compensate for attached papers and each thickened edge perforated for the purpose set forth, and

the surface of the sheet having adjacent to its upper edge and adjacent to the thickened edge the gummed spaces arranged at right angles to one another, whereby such papers when attached project at right angles over one another.

2. As a new article of manufacture, the loose sheet for a serial binder having one edge thickened to compensate for attached papers and each thickened edge perforated for the purpose set forth, the surface of the sheet having lines at right angles to each other adjacent to the upper edge and adjacent to the thickened edge to guide the application of papers to the sheet, and gummed spaces adjacent to each line for the attachment of the papers, whereby such papers when attached project at right angles over one another.

3. As a new article of manufacture, the loose sheet for a serial binder having one edge thickened to compensate for attached papers and each thickened edge perforated for the purpose set forth, the surface of the sheet having lines at right angles to each other adjacent to the upper edge and adjacent to the thickened edge to guide the application of papers to the sheet, and inscriptions adjacent to each line for directing the attachment of the papers, whereby such attached papers project at right angles over one another, substantially as herein set forth.

4. As a new article of manufacture, the loose sheet for a serial binder having one edge thickened to compensate for attached papers and each thickened edge perforated for the purpose set forth, the surface of the sheet having lines at right angles to each other adjacent to the upper edge and adjacent to the thickened edge to guide the application of papers to the sheet, gummed spaces adjacent to each line for the attachment of papers, whereby such papers when attached project at right angles over one another, and one of the outer corners of the sheet having a space indicated for a serial number, and for the purpose set forth.

700,507. HORSE-BOPPLE. MAX ELIEN, Denver, Colo. Filed July 22, 1901. Serial No. 60,006. (No model.)

Claim.—1. A horse-bopple, comprising checkins, a supporting-rod, means for securing the supporting-rod to a horse, a gripping device on the middle, draw-ropes extending through said gripping device and extending downward at opposite sides of a horse, means for releasing the gripping device, weights attached to said downwardly-extended portions, connections between said weights and the checkins, and draw-lines extended from the middle at opposite sides, the said draw-lines passing loosely through the eyes of one checkin at a side and engaging with the checkin of the other side, substantially as specified.

2. A horse-bopple, comprising a saddle adapted to fit over the withers of a horse, a breast-strap attached to the saddle, a body-strap attached to the saddle, a gripping device carried by the saddle, means for releasing the gripping device, draw-ropes extended through said gripping device and extended downward at opposite sides, weights attached to said opposite sides, checkins having connection with the weights, and means for drawing the checkins toward each other upon a downward movement of said saddle, substantially as specified.

3. A horse-bopple, comprising a saddle, a casing arranged on said saddle and having a gripping-jaw, a movable jaw in the casing, a draw-rope having connection with the movable jaw, draw-ropes passing between the jaws, weights attached to said ropes, checkins attached to the weights, and means for drawing the checkins toward each other on falling, substantially as specified.

4. A horse-bopple, comprising a saddle, a supporting-rod, means for securing the supporting-rod to a horse, a gripping device on the middle, means for releasing the gripping device, draw-ropes extended through said gripping device and extended downward at opposite sides of the horse, connections between said draw-ropes and the checkins, and draw-lines extended from the middle at opposite sides, the said draw-lines passing

loosely through the eyes of the checkins at one side and engaging with the checkins at the other side, substantially as specified.

5. A horse-bopple, comprising a saddle adapted to engage over the withers of a horse, a gripping device on the saddle, means for releasing the gripping device, draw-ropes extended through said gripping device and extended downward at opposite sides, weights attached to said downwardly-extended portions, the said weights having wide or broad base portions, checkins for engaging around the horse's legs, and straps extended from the said weights to engagement with the front and rear portions of the checkins, substantially as specified.

700,508. COMPOUND OR MULTIPLE-CYLINDER ENGINE. ISAAC ELIEN, Louisville, Ky. Filed May 22, 1901. Serial No. 61,468. (No model.)

Claim.—1. The combination of an oscillating cylinder having a ported transverse, with an oscillating steam-valve controlling the ports in said transverse and means for oscillating said valve simultaneously with but oppositely to the cylinder.

2. The combination with an oscillating cylinder having its inlet and outlet ports leading through one of its transverse, with an oscillating main valve fitted against the transverse and controlling the ports therein and means for oscillating said valve simultaneously with but oppositely to the cylinder, substantially as described.

3. The combination of an oscillating cylinder having a transverse and ports leading through said transverse, with a main-valve casing over the transverse, a rocking valve in said casing controlling the ports in the transverse, and means for oscillating said valve simultaneously with but oppositely to the transverse, substantially as described.

4. The combination of a valve-casing having a steam and an exhaust chamber, a cylinder, its ports, communicating with the valve-chamber, and a crank-shaft operated from the piston in said cylinder, with a valve within the valve-chamber having an inlet-chamber continuously communicating with the steam-supply and an outlet-port passing through the steam-space of the valve-casing but not communicating therewith, and an exhaust-chamber exterior to the steam-space with which said exhaust or outlet part of the valve communicates continuously, and means for oscillating said valve, substantially as described.

5. The combination of a cylinder, its ports extending through the cylinder-transverse, a valve-chamber over said ports and a crank-shaft operated from the piston in said cylinder, with a valve within the valve-chamber covering the said ports and having an inlet-chamber continuously communicating with the steam-supply and an outlet-port passing through the steam-space of the valve-casing but not communicating therewith, and an exhaust-chamber exterior to the steam-space with which said exhaust or outlet part of the valve communicates continuously, and means for oscillating said valve from said crank-shaft, substantially as described.

6. The combination of the cylinder, its opposite ports, a steam-chamber surrounding the outlet of said ports, and an exhaust-chamber exterior to the steam-chamber, with an oscillating valve in said steam-chamber covering the mouths of said cylinder-ports, said valve having inlet and outlet ports adapted to register alternately and successively with the cylinder-ports, the inlet-part of the valve being continuously in communication with the steam-space and the outlet-part of the valve extending through the steam-chamber to the exhaust-chamber, and means for operating said valve.

7. The combination of the cylinder, its opposite ports, a steam-chamber surrounding the outlet of said ports, and an exhaust-chamber exterior to the steam-chamber, with an oscillating valve in said steam-chamber, having inlet and outlet ports adapted to register successively and alternately with the cylinder-ports, said valve-inlet part continuously in communication with the said steam-chamber, and said valve-outlet part extending through the steam-chamber and communicating only with the exhaust-chamber, and means for operating said valve.

8. The combination of the main shaft, the gear thereon, the opposite fixed side plates, the oscillating cylinders journaled in and between said plates, the crank-shafts for the cylinders journaled in said plates, the pistons on said shafts meshing with said gear the cylinder-plates, the piston-rods connecting the pistons directly to adjoining crank-shafts, and the steam-ports leading through the transverse of the cylinders, and the combined steam supply and exhaust valve having inlet and exhaust ports adapted to register successively with the cylinder-ports, substantially as and for the purpose described.

9. The combination of an oscillating cylinder having steam inlet and exhaust ports leading through one of its transverse, a valve-casing fitted over said transverse, having a main steam-chamber and an exterior exhaust-chamber, a valve in said casing extending through the exhaust and steam chambers; said valve having one chamber always communicating with the steam-space, and another chamber extending through the steam-space and communicating with the exhaust-chamber only, said valve-chambers having ports in their inner ends adapted to alternately register with the cylinder-ports, and means for oscillating said valve, substantially as described.

10. The combination of the main shaft, the drum and gear loosely mounted thereon, the opposite side plates, the oscillating cylinders hung between said plates, the crank-shafts for the cylinders journaled in said plates, the pistons on said shafts meshing with said gear the cylinder-plates, the piston-rods connecting the pistons directly to adjoining crank-shafts, and the steam inlet and outlet ports leading through one transverse of each cylinder, and the steam supply and exhaust valve co-operating with the ported transverse, substantially as and for the purpose described.

11. The herein-described engine comprising a main shaft, a gear and drum or fly-wheel loosely mounted thereon, a pair of plates fixed thereon, a series of crank-shafts journaled in said plates, pistons on said shafts meshing with said gear, an oscillating cylinder for each shaft journaled between said plates, the cylinder-plates and piston-rods, and the cylinder-ports extending through the outermost transverse of each cylinder; with the valve-casings attached to the outer plate over the cylinder-transverse, the steam and exhaust chambers in said valve-casings, the valves in said chambers constructed substantially as described, and the valve-actuating devices connected to and operated by the respective crank-shafts, for the purpose and substantially as described.

700,509. DOLLER, ALBERT F. KNAGGER and HERMAN O. WALK. Invention. Wm. Filed Sept. 16, 1901. Serial No. 75,304. (No model.)

Claim.—1. A roller comprising separable sections each formed with an annular groove on its inner face, and one of said sections having a threaded sleeve extending into the other section, legs diametrically arranged on the said sleeve adapted to fit in corresponding recesses in the opposite section, a yielding tire flanged to fit said grooves, and an internally-threaded ring fitting on the threaded end of the sleeve.

2. A roller comprising separable sections each formed on its inner face with an annular groove, and one of said sections having a threaded sleeve extending into the other section, a rubber tire formed with annular flanges fitting said grooves, radial legs on the sections to prevent movement of the tire except with the roller, and means for preventing the roller-sections from independent rotary movement.

700,510. TUBE-EXPANDER. ELWOOD L. KIMBLE. Invention. W. Va. Filed June 8, 1901. Serial No. 68,088. (No model.)

Claim.—In a tube-expander, the combination with a tubular handle of a head thereon having a recess in the end thereof, a tubular expander proper having distal ends extending from the inner end thereof, a head at one end of said expander proper extending over the end of the distal, rollers adapted to be inserted longitudinally under the head and into the distal, said head being fixed in the recess in the handle whereby longitudinal movement of the rollers is prevented, means for locking the head in the recess, a mandrel extending through the handle and the expander proper, and means for revolving the handle.

700,510.

700,511. FAN-GOVERNOR. HENRY KOEN, Railway, N. J., assignor to Regina Motor Box Company, Railway, N. J., a Corporation of New Jersey. Filed July 4, 1901. Serial No. 67,088. (No model.)

Claim.—1. The combination with the governor-spindle of a frame held to turn with the spindle, wings pivoted to the frame at a distance from the spindle, springs connecting said wings and a shifting mechanism turning with the wings and movable thereon for changing the center of gravity of the wings.

2. The combination with the governor-spindle of a frame held to turn with said spindle, wings pivoted to said frame at a distance from the spindle, shifting members carried by the wings and adapted to change the location of the center of gravity thereof and means for adjusting said shifting members.

3. The combination with the governor-spindle of a frame held to turn with said spindle, wings pivoted to the frame at a distance from the spindle, shifting means movable on the wings toward and from the pivots of the wings and mechanism for changing the position of said shifting means.

4. The combination with the governor-spindle of a frame held to turn with the spindle, wings pivoted to the frame at a distance from the spindle, shifting means movable on the wings toward and from their pivots and an operating-slide connected with said shifting means and movable parallel with the governor-spindle.

5. The combination with the governor-spindle of a frame held to rotate therewith, wings pivoted to said frame at a distance from the spindle

the shaft axis parallel with the spindle, shifting means movable on the wings toward and from their pivots, and an operating-slide connected with said shifting means and movable lengthwise upon the governor-spindle and upon the wing-pivots.

6. The combination with the governor-spindle and means for rotating it, of a frame held to turn with said spindle, wings pivoted to said frame at a distance from the spindle, springs connecting said wings, and a shifting device for moving the attached ends of the springs toward and from the pivots of the respective wings.

7. The combination with the governor-spindle and means for rotating it, of a frame held to turn with said spindle, wings pivoted to said frame at a distance from the spindle, springs connecting said wings, and means carried by the wings, for adjusting said springs.

8. The combination with the governor-spindle and means for rotating it, of a frame held to turn with said spindle, wings pivoted to said frame at a distance from the spindle, springs connecting said wings, each wing having a slot or slitway extending toward and from its pivot, pins or attaching members movable in said slitways and each connected with one end of a spring, and a shifting device for moving said attaching members in or out.

9. The combination with the governor-spindle and means for rotating it, of a frame held to turn with said spindle, wings pivoted to said frame at a distance from the spindle, springs connecting said wings, a slide movable parallel with the governor-spindle, means for operating said slide, and a shifting device, actuated by the movement of the slide, for moving the attached ends of the springs toward and from the pivots of the respective wings.

10. The combination with the governor-spindle and means for rotating it, of a frame held to turn with the spindle and provided with bars extending parallel with the spindle, a slide movable lengthwise of said bars, means for actuating the slide, wings pivoted to said frame, springs connecting the wings, and a shifting device operated by the movement of the slide, for moving the spring ends toward or from the pivots of the respective wings.

11. The combination with the governor-spindle and means for rotating it, of a frame held to turn with the spindle and provided with bars extending parallel with the spindle, a slide movable lengthwise of said bars, means for actuating the slide, wings pivoted to said frame, attaching devices movable toward and from their pivots, springs each of which has one end secured to a wing directly and the other end to the attaching device on the other wing, and a shifting device, operated by the movement of the slide, for moving the said attaching devices toward or from the pivots of the respective wings.

12. The combination with the governor-spindle and means for rotating it, of a frame held to turn with the spindle and provided with bars extending parallel with the spindle, a slide movable lengthwise of said bars, and of the spindle, and provided with grooved collars at the spindle and bars, an actuating device for moving the slide, provided with a projection engaging the collar at the spindle, wings pivoted to the frame, bell-crank levers fulcrumed on the wings and provided with projections engaging the collar at the bars, and springs connecting the wings and each having one end controlled by said bell-crank lever to vary the working tension of the springs.

700,512. PROCESS OF MAKING SULFURIC ACID AND SULFUR ANHYDRIDE. GUSTAVUS KRAMER and EDUARD H. VAN BUREN. Invention. Invented in the State of Germany, assigned to Farbwerke, vorm. Meister, Lucius & Brüning, Höchst-am-Main, Germany, a Corporation of Germany. Filed Mar. 4, 1902. Serial No. 68,081. (No specimens.)

Claim.—The herein-described process of making sulfuric acid and sulfur anhydride with simultaneous combination of the unsulfated sulfur dioxide contained in the burnt pyrites, which consists in bringing pyrites-burner gases at a low temperature into contact with burnt pyrites containing free sulfur dioxide, whereby sulfur dioxide is fixed by the burnt pyrites and in then applying a higher temperature the fixed sulfur dioxide being again separated as sulfuric anhydride, substantially as set forth.

700,513. ROLL. JENNIS P. LAWRENCE, Patent. N. J. Filed June 29, 1901. Serial No. 68,086. (No model.)

Claim.—A roll, comprising conical sections placed together edge to edge so as to form wheel members, endless bands of resilient material encircling said wheel members in such manner as to secure a plurality of said wheel members together and also to press together the conical sections in each wheel member, bolts disposed substantially at right angles to the axis of said wheel members for further securing together the conical sections of each wheel member, and longitudinal rods passing through all of said wheel members parallel with the axis thereof for the purpose of clamping said wheel members together.

700,514. VEHICLE-WHEEL. GEORGE S. LAM, Invention. N. J., assignor to Wheel Within Wheel Company, New York, N. Y., a Corporation of New Jersey. Filed Nov. 1, 1901. Serial No. 68,778. (No model.)

Claim.—1. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the hub member comprising two hub-sections, a plurality of spokes, and a rim, the said spokes having portions thereof located between the said hub-sections to form spacing-pieces therefor, and secured to the said hub-sections.

2. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having an annular cushioning device between them, the hub member comprising two hub-sections, each having a plurality of oppositely-disposed radial arms, a spacing-piece between each of the said opposed radial arms, said spacing-piece comprising the inner ends of spokes, bolts connecting the hub-sections together and passing through said spacing-pieces, and a rim supported by the opposite ends of said spokes.

3. In a wheel, the combination with a hub, spokes and a rim, of a tire-rim, an annular cushioning device between the tire-rim and the first said rim, a floating plate, spokes comprising separable members arranged on either side of the said annular cushioning device, and connecting the said floating plate and tire-rim together, and an intermediate guide-plate between the floating plate and the hub.

4. In a wheel, the combination with a hub, spokes and a rim, of a tire-rim, an annular cushioning device between the tire-rim and the first said rim, a floating plate, spokes comprising, each, two members connected together, and connecting said floating plate and said tire-rim, said members arranged on opposite sides of said annular cushioning device, and an intermediate guide-plate between the floating plate and the hub.

5. In a wheel, the combination with a hub, spokes and a rim, of a tire-rim, an annular cushioning device between the tire-rim and the first

mid rim, a floating plate, spokes comprising each two members, one member of each spoke secured to the mid floating plate and mid tire-rim, and arranged to pass on one and the same side of said annular cushioning device, and the other spoke member removably secured to the first mid spoke member, and arranged upon the opposite side of said cushioning device, whereby the two members of said mid spokes surround said cushioning device; and an intermediate guide-plate between the floating plate and the hub.

6. In a wheel, the combination with a hub, spokes and a rim, of a tire-rim, an annular cushioning device between the tire-rim and the first mid rim, a floating plate, spokes radiating from said floating plate, each spoke comprising two members, secured together, and together surrounding the said cushioning device, the mid spokes having each two divergent branches, and secured at the outer ends of the mid branches to the mid tire-rim; and an intermediate guide-plate between the floating plate and the hub.

7. The combination in a wheel comprising two members, of a hub comprising two hub-sections, spacing-pieces between them and secured thereto, said spacing-pieces comprising the inner ends of spokes, a rim to which the outer ends of said spokes are secured, said hub, spokes and rim comprising one of said wheel members; a tire-rim, a floating plate located within said hub, spokes connecting said floating plate with said tire-rim, said spokes comprising separable members, the mid tire-rim, floating plate and hub-named spokes comprising the other of said wheel members; an annular cushioning device between the rim of said first-named wheel member and the tire-rim of the other mid wheel member, and located between the mid separable spoke-sections, and an intermediate guide-plate between the mid hub and the mid floating plate.

700,515. VEHICLE-WHEEL. GEORGE S. LEE, Hawthorne, N. Y., assignor to Wheel Within Wheel Company, New York, N. Y., a Corporation of New Jersey. Filed Dec. 9, 1901. Serial No. 84,917. (No model.)

Claim.—1. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the hub member comprising two hub-sections, a plurality of spokes, and a rim, one of said hub-sections provided with a central orifice adapted to receive a projection upon the other hub-section, and the mid other section provided with a central projection adapted to pass through said orifice; and a locking device between the first mid hub-section and the projection of the other mid hub-section.

2. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the hub member comprising two hub-sections, a plurality of spokes, and a rim, one of said hub-sections provided with a central orifice adapted to receive a projection upon the other hub-section, and the mid other section provided with a central projection adapted to pass through said orifice; and a nut mounted upon the projection of the one section, and engaging the other mid section.

3. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the hub member comprising two hub-sections, a plurality of spokes, and a rim, one of said hub-sections provided with a central orifice adapted to receive a projection upon the other hub-section, and the mid other section provided with a central projection adapted to pass through said orifice, said central projection having a portion concentric of the axis of the hub, whereby the two hub-sections are held together against relative rotation; and means whereby the mid sections are held together against relative movement longitudinally of their axis of rotation.

4. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the hub member comprising two hub-sections, a plurality of spokes, and a rim, one of said hub-sections provided with a central orifice adapted to receive a projection upon the other hub-section, and the mid other section provided with a central projection adapted to pass through said orifice; mid central projection having a portion concentric of the axis of the hub, whereby the two hub-sections are held together against relative rotation; and a nut mounted upon the projection of the one section and engaging the other mid section.

5. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the hub member comprising two hub-sections, a plurality of

spokes, and a rim, one of said hub-sections provided with a central projection adapted to pass through an orifice in the other section, and having a shouldered portion, and the mid other section provided with a central orifice to receive such shouldered projection, and a nut mounted upon the projection of the one section, and engaging the other mid section.

6. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the hub member comprising two hub-sections, a plurality of spokes, and a rim, one of said hub-sections provided with a central projection adapted to pass through an orifice in the other section, and having a shouldered portion concentric of the axis of the hub, and the mid other section provided with a central orifice to receive such projection, and a nut mounted upon the projection of the one section, and engaging the other mid section.

7. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the hub member comprising two hub-sections, a plurality of spokes, and a rim, one of said hub-sections provided with a central projection adapted to pass through an orifice in the other section, and having two projecting ears, and the mid other section provided with a central orifice to receive such projection and having recesses to receive the said ears, and a nut mounted on the projection of the one section and engaging the other mid section.

8. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the hub member comprising two hub-sections, a plurality of spokes, and a rim, one of said hub-sections provided with a central orifice adapted to receive a projection upon the other hub-section, and the mid other section provided with a central projection adapted to pass through said orifice; and a locking device between the first mid hub-section and the projection of the other mid hub-section; the said spokes being straight-line compression-spokes and arranged in pairs, each pair converging from the opposite hub-sections to the mid rim.

700,516. VEHICLE-WHEEL. GEORGE S. LEE, Hawthorne, N. Y., assignor to Wheel Within Wheel Company, New York, N. Y., a Corporation of New Jersey. Filed Dec. 31, 1901. Serial No. 87,961. (No model.)

Claim.—1. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the tire member comprising a plurality of spokes having portions removable therefrom, and a rim secured to said spokes having a removable flange, said flange having the removable portions of said spokes secured thereto.

2. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having an annular cushioning device between them, the tire member comprising a plurality of spokes having portions removable therefrom, said spokes having the removable portions of the spokes opposite thereto, surrounding the mid annular cushioning device, a rim secured to said spokes, and having a removable flange, said flange having the removable portions of said spokes secured thereto, and bolts for securing the removable flange and the removable spoke portions to the mid rim and spokes.

3. A wheel comprising two relatively movable members, one a tire member, and the other a hub member, and having an annular cushioning device between them, the tire member comprising a rim and a plurality of spokes connected thereto, said spokes arranged to surround said cushioning device and leveled away at their outer central portions so as to form a support for said cushioning device at various points around the circle, but to permit said cushioning device to bear directly against the inner face of said rim.

4. In a wheel, the combination with a hub, spokes, and a rim, of an outer tire-rim, an annular cushioning device located between, and bearing directly against, said rim and the inner face of said tire-rim, a floating

plate, and spokes surrounding said cushioning device and connecting said floating plate and said tire-rim together.

5. In a wheel, the combination with a hub, spokes, and a rim, of an outer tire-rim, an annular cushioning device located between, and bearing directly against, said first-named rim and the inner face of said tire-rim, a floating plate, and spokes connecting said floating plate and said tire-rim together, said spokes surrounding said cushioning device, and engaging same at various points around the circle.

6. In a wheel, the combination with a hub, spokes, and a rim, of an outer tire-rim having a removable flange, a floating plate, a plurality of spokes secured to the said tire-rim and to said floating plate, said spokes having each a removable portion, all of which said portions are secured to the mid removable rim-flange, an annular cushioning device arranged between, and adapted to bear directly against, the mid first-named rim and the inner face of said outer tire-rim, a plurality of bolts through the outer tire-rim, securing the removable flange thereto, and a plurality of bolts securing the removable portions of the spokes to the main portions thereof.

700,517. LAMP-HANGER. THOMAS LUDWIG and LEONARD L. WHITE, Wheeling, Pa. Filed Sept. 8, 1891. Serial No. 74,821. (No model.)

Claim.—1. In a lamp-hanger, the combination with a spring-actuated drum, of a supporting-cord adapted to be wound thereon, a guide-finger independent from the drum and adapted to move longitudinally thereof, in contact with the cord wound thereon, and means independent of the drum for imparting yielding pressure of the guide-finger against the cord-windings; substantially as specified.

2. In a lamp-hanger, the combination with a spring-actuated drum, of a supporting-cord adapted to be wound thereon, a guide-finger independent from the drum and adapted to move longitudinally thereof, and a spring for normally forcing said guide toward one edge of said drum; substantially as specified.

3. A lamp-hanger comprising a frame, a spring-actuated drum rotatably mounted therein, a supporting-cord wound upon said drum, a cross-bar at one side of said drum, a guiding-finger adapted to contact with said cord and slidably mounted upon said cross-bar, and a spring for pressing said finger in one direction; substantially as specified.

4. A lamp-hanger comprising a frame, a spring-actuated drum rotatably mounted therein, a supporting-cord wound upon said drum, a cross-bar at one side of said drum, a guiding-finger adapted to contact with said cord and slidably mounted upon said cross-bar, a spring for pressing said finger in one direction, an opposite corresponding guide-finger upon the opposite side of the drum, a spring for pressing said opposite finger in the direction opposite to that of the first-mentioned finger; substantially as specified.

5. A lamp-hanger comprising a frame, a spring-actuated drum rotatably mounted therein, a supporting-cord wound upon said drum, a cross-bar at one side of said drum, a guiding-finger adapted to contact with said cord and slidably mounted upon said cross-bar, a spring for pressing said finger in one direction, an opposite corresponding guide-finger upon the opposite side of the drum, a spring for pressing said opposite finger in the direction opposite to that of the first-mentioned finger, and guide-recesses supported by the frame adjacent to the longitudinal center of said drum; substantially as specified.

6. In a lamp-hanger, the combination with a supporting-drum, a cord adapted to be wound thereon and passed therethrough, of a spider having arms adapted to be removably secured to said drum and carrying the outer end of the actuating-spring for the drum at a distance from the inner face thereof, a spindle for said drum to which the opposite end of said spring is secured, and means for securing said spindle against rotation; substantially as specified.

7. In a lamp-hanger, the combination with a supporting-drum and

cord adapted to be wound thereon, of a spider having arms adapted to be secured to said drum and carrying one end of the actuating-spring for the drum at a distance from the inner face thereof, a spindle for said drum to which the opposite end of said spring is secured, a frame for said drum having legs opposite one end of said spindle, and a securing-pin passed through said legs and spindle; substantially as specified.

8. A lamp-hanger comprising a frame, a spring-actuated drum centrally mounted therein, cross-bars at opposite sides of said drum, a supporting-cord extending from the opposite edge portions of said drum, guide-fingers slidably mounted upon said cross-bars, and a coiled spring surrounding said cross-bars and adapted to force said fingers toward the opposite ends of the drum; substantially as specified.

9. A lamp-hanger comprising a frame, a spring-actuated drum centrally mounted therein, cross-bars at opposite sides of said drum, a supporting-cord extending from the opposite edge portions of said drum, guide-fingers slidably mounted upon said cross-bars, a coiled spring surrounding said cross-bars and adapted to force said fingers toward the opposite ends of the drum, and oppositely-disposed guide-recesses carried by said frame at each side of said drum and at the longitudinal center thereof; substantially as specified.

700,518. BOTTLE-MAKING AND WASHING MACHINE. CHAS. E. LADD, Cleveland, Ohio. Filed Jan. 3, 1902. Serial No. 93,992. (No model.)

Claim.—1. In bottle-makers, a suitable tank, an endless bottle-carrier, endless tracks supporting the carrier at all points in its travel and rollers supporting the carrier on the tank and arranged to guide the lead and prevent friction, substantially as described.

2. The tank and the endless tracks thereon, an endless carrier supported at its edges on said tracks, and stationary parts around which the carrier is wound, substantially as described.

3. The tank and the endless tracks thereon, in combination with an endless carrier having rollers traveling on said tracks the entire length of the carrier, substantially as described.

4. In bottle-washing machines, an endless carrier comprising chains at its edges and cross-pieces connecting said chains constructed in very bottles, endless tracks in which said chains travel, rollers to support the said chains throughout the entire length of their travel on said tracks, and drive-wheels engaging said chains and moving the carrier, substantially as described.

5. The tank and the endless tracks thereon constructed to support a series of rollers, in combination with an endless carrier engaged at its edges on said tracks and rollers supporting the carrier thereon, and drive mechanism in the line of said tracks engaging the said carrier between said rollers, substantially as described.

6. The tank and the endless tracks thereon having a separate sec-

tion at one of its ends and means to adjust said separate section to lengthen or shorten the line of travel, substantially as described.

7. The tank having two compartments, the endless track supported on said tank and extending to the division-wall between said compartments and in position to discharge into the rear compartment, in combination with an endless carrier on said tank provided with bottle-holding receptacles constructed to discharge the bottles by gravity, and means to confine the bottles in their receptacles terminating at the edge of said second compartment, substantially as described.

8. The tank having a side recess extending laterally beyond the body of the tank and open thereto, in combination with an endless carrier and supports therefor arranged to bring the carrier over the portion of the tank having said side recess and then closing the space entered by said recess from the top, substantially as described.

700,519. AIR-HEATER. ARTHUR H. LOVEDAY, Dallas, N. J. Filed Dec. 17, 1901. Serial No. 88,306. (No model.)

Claim.—1. An air-heater, having a series of air-tubes, each connected at one end with a cold-air-supply chamber, and at the other end with a distributing-pipe for conducting the heated air to a room, the said air-tubes being arranged side by side and extending around the fire-box, and sub-pit and forming a combustion-chamber above the fire-box, as set forth.

2. An air-heater, having a series of air-tubes, each connected at one end with a cold-air-supply chamber, and at the other end with a distributing-pipe for conducting the heated air to a room, the air-tubes having their lower portions extending along the outside of the fire-box and sub-pit, and the upper portions bent inwardly into contact with each other to form a drum or combustion-chamber above the fire-box and thence extended vertically, as set forth.

3. An air-heater, having a series of air-tubes, each connected at one end with a cold-air-supply chamber, and at the other end with a distributing-pipe for conducting the heated air to a room, the air-tubes having their lower portions extending along the outside of the fire-box and sub-pit, and the upper portions bent inwardly into contact with each other to form a drum or combustion-chamber above the fire-box and thence extended vertically, and a shell surrounding the air-tubes above the fire-box to form a heating-chamber between the shell and the outer sides of the upper bent portions of the air-tubes, as set forth.

4. An air-heater, having a series of air-tubes, each connected at one end with a cold-air-supply chamber, and at the other end with a distributing-pipe for conducting the heated air to a room, the air-tubes having their lower portions extending along the outside of the fire-box and sub-pit, and the upper portions bent inwardly into contact with each other to form a drum or combustion-chamber above the fire-box, a shell surrounding the air-tubes above the fire-box to form a heating-chamber between the shell and the outer sides of the upper bent portions of the air-tubes and through the top of which the upper ends of the air-tubes extend, and a smoke-flue leading from the combustion-chamber and extending through the said heating-chamber, as set forth.

5. An air-heater, comprising a cold-air-supply chamber, a base-plate set over the said chamber, a fire-box and sub-pit on the said base-plate, and a series of air-tubes opening through the base-plate into the cold-air-supply chamber, the air-tubes extending upwardly along the outside of the sub-pit and fire-box, to then extend inwardly and upwardly into contact with each other to form a combustion-chamber over the fire-box and thence extended vertically, as set forth.

6. An air-heater, comprising a fire-box, an sub-pit below the fire-box, a series of air-tubes extending along the outside of the sub-pit and fire-box and then bent inwardly into contact with each other above the fire-box to form a combustion-chamber above the same, the lower ends of the tubes being open for connection with a cold-air chamber and their upper ends adapted to be each connected with a distributing-pipe, a shell surrounding the upper portion of the said tubes and forming a heating-chamber around the same and through the top of which the upper ends of the air-tubes extend, and a smoke-flue leading from the combustion-chamber and extending into the heating-chamber to the front of the same and thence out through the rear thereof, as set forth.

700,520. SAIL FOR MARINE VESSELS. RICHARD LINDQUIST, Laguna de Turkey, Mexico. Filed July 24, 1901. Serial No. 88,308. (No model.)

Claim.—1. The combination with a mast, a boom and a gaff, of a sail in two parts, connected at their adjacent vertical edges, the main part of the sail being fastened to the boom and mast and having a square head running along and fastened to the gaff, and the other part having a jib-head fastened to the peak of the gaff, and an auxiliary boom adjustably mounted on the main boom, to which auxiliary boom the foot of the said other sail part is fastened.

2. The combination of a boom, an auxiliary boom arranged to swing thereon, means for independently trimming said booms, and a sail formed in two parts respectively connected with the said booms.

700,521. PROCESS OF DYING BY INDOLE. SUMNER LORAN, Trans. near Lake, Austria-Hungary. Filed July 11, 1901. Serial No. 87,304. (No specimens.)

Claim.—1. The process of dyeing textile material, which consists in first treating the whole of the material with a mordant containing naphthol, then printing portions of the material with a dye mixture containing the said dye and a reserve, so that the required color is formed on the material, then dyeing the material with indigo, and finally treating it with acid, substantially as set forth.

2. The process of dyeing textile material, which consists in first treating the whole of the material with a mordant containing naphthol and ferrocyanide of potassium, then printing portions of the material with a dye mixture containing the said dye and a reserve, so that the required color is formed on the material, then dyeing the material with indigo, and finally treating it with acid, substantially as set forth.

700,522. EXTENSIBLE TROUGH. FREDERICK MAGNUS, Elmsted, N. J. Filed Aug. 5, 1901. Serial No. 79,894. (No model.)

Claim.—An extensible trough comprising a plurality of counterpart sheet-metal semicircular trough-sections, having their upper opposite edges bent at right angles and being provided at each end with an inwardly-extending rib forming upon the outside a groove, in combination with two counterpart semicircular end panels provided with peripheral grooves adapted to receive the inwardly-extending ribs of aforementioned trough-

sections, an upper strengthening-bar extending across and beyond each end panel, each bar being provided with end perforations, U-shaped loop-bars extending within aforementioned grooves anteriorly of each end trough-section, the upper ends of said loop-bars extending through said upper strengthening-bars and being secured by means of suitable nuts, a packing-strip interposed between the united ends of said trough-sections where they join one another, a semicircular grooved strip disposed laterally above each point of union between two trough-sections to receive the aforementioned inwardly-extending ribs of the uppermost trough-section, a transverse spacer-bar provided with downwardly-extending cam adapted to bear against said semicircular ribs at the upper ends, said spacer being provided with extending perforated ends and a U-shaped intermediate loop-bar within the groove of the outer trough-section, passing through the perforated ends of said spacer and being suitably secured in the manner set forth.

700,523. REVOLVING BOOK-SUPPORTER. ORAN A. HANSEN and JERAM B. BURNHAM, Washington, D. C., assignors of one-fourth to Richard J. Burnham, Washington, D. C. Filed Feb. 25, 1902. Serial No. 85,289. (No model.)

Claim.—1. In a book-supporter, the combination with a suitable base, of a rest for the book, an extensible slide at each side of the rest, to adapt it to books of different widths, and means carried by the extensible slides for clamping the leaves at the corners thereof, said means being adjustable transversely to said slides.

2. In a book-supporter, the combination with a suitable base, of a rest for the book, an extensible slide at each side of the rest, and spring leaf-clamping devices, carried by the extensible slides and adjustable transversely thereto.

3. In a book-supporter, the combination with a suitable base, of a rest for the book, an extensible slide at each side of the rest, an adjustable leaf-clamping device slidable in the upper end of each extensible slide, and a leaf-clamping device carried at the lower end of each extensible slide.

4. In a book-supporter, the combination with a suitable base, of a rest for the book, an extensible slide at each side of the rest, and an adjustable leaf-clamping device slidable in the upper and lower end of each extensible slide, whereby books of different lengths may be supported, and the lower edge of the book brought close to the surface of the object upon which the device is placed.

5. In a book-supporter, the combination with a suitable base, of a rest for the book, an extensible slide at each side of the rest, said slide consisting of a rectangularly-bored tube provided with arms adapted to slide in guide-ways on the rest, and leaf-clamping devices carried by the extensible slides and adjustable transversely thereto.

6. In a book-supporter, the combination with a suitable base, of a rest for the book, an extensible slide at each side of the rest, said slide consisting of a rectangularly-bored tube having arms adapted to slide in guide-ways on the rest, and spring leaf-clamping devices having arms slidable in the ends of the extensible slides.

700,524. STRIP-PITCHER. ROBERT J. HANCOCK, Rochester, N. Y. Filed Jan. 29, 1902. Serial No. 91,912. (No model.)

Claim.—1. A pitcher or other vessel provided with a spout having a supplemental spout conforming to the spout in said vessel and pivoted thereto, and means for positively operating said supplemental spout, substantially as shown and described.

2. A pitcher or other vessel provided with a lid, a spout, a supplemental spout pivoted thereto and connected to said lid by an arm and adapted to be automatically and simultaneously operated by the opening and closing of said lid, substantially as shown and described.

3. A pitcher or other vessel provided with a lid, a spout, a supplemental spout pivoted thereto and connected to said lid by an arm and adapted to be automatically and simultaneously operated by the opening and closing of said lid, substantially as shown and described.

4. A pitcher or other vessel provided with a spout, a supplemental spout pivoted thereto having a flange adapted to rest on the top thereof, and means for operating said supplemental spout, substantially as shown and described.

5. A pitcher or other vessel provided with a lid, a spout, a supplemental spout pivoted thereto having a flange adapted to rest on the top thereof, and means connecting said lid and supplemental spout, whereby when the lid is opened or closed thereby it simultaneously operates said spout, substantially as shown and described.

6. A pitcher or other vessel provided with a spout, a supplemental spout pivoted thereto provided with an arm carrying a link, a lid provided with an arm the free end of which is pivoted to said link, substantially as shown and described.

700,525. CASH-REGISTER. ALEXANDER W. HARR, Dayton, Ohio, assignor, by mesne assignments, to the National Cash Register Company, Jersey City, N. J., a Corporation of New Jersey. Filed Jan. 29, 1902. Serial No. 887,198. (No model.)

Claim.—1. In a cash-register, the combination with a registering mechanism, of a key-coupler, a special key-lever having a rigid projection arranged to be moved into the path of the coupler without engaging it, and a series of cam-bays adapted to operate said coupler.

2. In a machine of the character described the combination with a

series of cam or numbered keys and a registering mechanism, of a series of special keys, indicators cooperating respectively therewith and arranged to be set for movement to indicating position by the operation of said special keys, means controlled by the cam-keys for registering and indicating the amount of the transaction and expending the indicator previously set by the operation of the special keys, and locking means controlled by the special keys to prevent the operation of the cam or numbered keys until a special key has been operated.

3. In a cash-register, the combination with a registering mechanism, of a pivoted key-coupler, a special key-lever pivoted concentrically to the coupler and formed with a rigid projection that may be moved into the path of the same without engaging it, a key for setting said lever and a series of amount-keys for operating said coupler.

4. In a cash-register, the combination with a registering mechanism, of a pivoted key-coupler, a special key-lever pivoted concentrically to the coupler and so formed that it may be moved into the path of the same without engaging it, a special key for operating said lever, a special indicator cooperating with said lever and a series of amount-keys arranged to operate said coupler.

5. In a cash-register, the combination with a registering mechanism, of a key-coupler, a special key-lever having a hook and a notched portion whereby it may be moved into cooperative relation with the coupler without engaging it, a series of amount-keys for operating said coupler, and a special key for setting the special key-lever.

6. In a cash-register, the combination with a registering mechanism, of a series of amount-keys, a number common to all of said keys and arranged to be moved by the same, special key-levers arranged to be coupled to said number, special keys for setting said levers, and a lock for said common number, arranged to be operated by the special keys.

7. The combination with the type-carrier, of a sliding plate having inclined slots, means connecting said type-carrier and plate, vertically-sliding bars X having finger-pieces for depressing them and pins which project into the inclined slots, and a detent plate or wing G cooperating with notches F formed in the bars X.

8. The combination with a type-carrier, of a sliding plate having inclined slots, means connecting said type-carrier and plate, a series of special keys having projections which enter the slots of said plate, a detent plate or wing cooperating with said keys, a series of cam-keys and means operated by the cam-keys for disengaging the detent-plate from the special keys.

9. The combination with a type-carrier of a series of special keys for operating the same, a series of cam-keys, a movable member common to said cam-keys and provided with a locking projection, a pivoted locking-lever arranged to engage said projection, a rock-shaft carrying said lever, and projections mounted on the special keys and adapted to rock said shaft.

10. The combination with a type-carrier, of a series of special keys for operating the same, a series of cam-keys, a movable member common to said cam-keys, and provided with a locking projection, a locking-lever arranged to engage said projection, a rock-shaft carrying said lever and provided with an operating-rib and pins mounted on the special keys so as to engage said rib and rock the shaft.

11. The combination with a type-carrier of a series of special keys for operating the same, a locking-plate for holding said keys in their depressed position, a series of cam-keys, a movable member common to all of the cam-keys, and a cam mounted on the same, and arranged to engage and operate the locking-plate.

12. The combination with a series of cam-keys, of a series of special keys, means for preventing the operation of a cam-key until a special key is operated, devices for locking the special keys in their depressed position, a movable member common to all of the cam-keys, and a cam mounted on said member and adapted to operate the locking devices.

13. The combination with a series of cam-keys, of a series of special keys, the detent-plate G cooperating with the special keys, the universal bar N operated by the cam-keys and provided with an extension-arm, the plate L pivoted on the arm and formed with the cam N cooperating with the detent G.

14. The combination with a series of cam-keys, of a series of special keys, the special key-levers A, the universal bar N, a series of nested sleeves extending across the machine, means connecting said sleeves to the special keys at one end and devices mounted on said sleeves at their opposite ends for operating the keys A.

15. The combination of the special type-wheel N, the shaft F geared thereto and provided with the pinion T, the sliding plate V provided with the inclined slot X and having the rack U meshing with the pinion T, the vertically-sliding key-bar E provided with finger-pieces for depressing them against the resistance of their resetting-springs E' and having the pin Y cooperating with the slot X in the plate V, the detent-plate G cooperating with the notches F in the key-bar E, and means actuated by the cam-keys of the machine to disengage the detent-plate from the notches in the key-bar.

16. The combination of the special type-wheel N, the shaft F geared thereto and provided with the pinion T, the sliding plate V provided with the inclined slot X and having the rack U meshing with the pinion T, the vertically-sliding key-bar E provided with finger-pieces for depressing them against the resistance of their resetting-springs E' and having the pin Y cooperating with the slot X in the plate V, the detent-plate G cooperating with the notches F in the key-bar E, and means actuated by the cam-keys of the machine to disengage the detent-plate from the notches in the key-bar.

17. The combination of the special type-wheel N, the shaft F geared thereto and provided with the pinion T, the sliding plate V provided with the inclined slot X and having the rack U meshing with the pinion T, the vertically-sliding key-bar E provided with finger-pieces for depressing them against the resistance of their resetting-springs E' and having the pin Y cooperating with the slot X in the plate V, the detent-plate G cooperating with the notches F in the key-bar E, the universal bar N of the machine operated by the cam-keys A thereof and provided with the forwardly-extending arm M, and the plate L pivoted upon the arm M and provided with the cam K cooperating with the pin J upon the detent-plate G for the purpose described.

18. The combination, with the cam-keys and the universal bar N operated thereby and provided with the forwardly-extending arm M, of the vertically-sliding key-bars E of the special keys, the rock-shaft T adapted to be rocked by the depression of any one of said bars, and the arm W carried by said rock-shaft and cooperating with a projection M' on the arm M.

19. The combination, with the cam-key levers A, and the universal bar N cooperating therewith, of the special key-levers A' also cooperating with the bar N, the indicator-rod and indicator cooperating with the bar N, the indicator-rod and indicator cooperating with said levers A', the special keys, and the rock-shaft and sleeves provided at one end with arms or projections cooperating with the special keys and at their opposite ends with arms or projections cooperating with the key-levers A' for the purpose described.

20. The combination, with the cam-key levers A and the universal bar N cooperating therewith, of the special key-levers A' also cooperating with the bar N, the indicator-rod and indicator cooperating with the bar N, the indicator-rod and indicator cooperating with said levers A', the special keys, the rock-shaft T and the sleeves thereon, the plate N carried by said shaft and sleeves and cooperating with the pin K upon the key-bar E, the shaft F and sleeves thereon, connected respectively to the shaft F and the sleeves, and the arms Q that upon the shaft F and in sleeves and cooperating with the levers A', for the purpose described.

700,526. GRINDING OR CRUSHING HEAD. VOLNEY W. MARR, JR., New York, N. Y. Filed Apr. 26, 1901. Serial No. 57,507. (No model.)

Claim.—1. A grinding or crushing head comprising a central core having a number of dovetailed grooves extending from the top to a point near the bottom each having an abutting shoulder at its lower end, a set of external segments, made wider at the bottom than at the top, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves in the core, and another set of external segments, made wider at the top than at the bottom, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves of the core, the several segments of said sets being alternately disposed about the core, and abutting together, and the lower ends of the ribs abutting against the abutting shoulders at the lower ends of the grooves, substantially as described.

2. A grinding or crushing head comprising a central core having a number of dovetailed grooves extending from the top to a point near the bottom, made wider at their upper ends than at their lower ends and having an abutting shoulder at their lower ends, a set of external segments, made wider at the bottom than at the top, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves in the core, and another set of external segments, made wider at the top than at the bottom, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves of the core, the several segments of said sets being alternately disposed about the core and abutting together, and the lower ends of the ribs abutting against the abutting shoulders at the lower ends of the grooves, substantially as described.

3. A grinding or crushing head comprising a central core having a number of dovetailed grooves extending from the top to a point near the bottom each having an abutting shoulder at its lower end, a set of external segments, made wider at the bottom than at the top, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves in the core, and another set of external segments, made wider at the top than at the bottom, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves of the core, the several segments of said sets being alternately disposed about the core and abutting together, and the lower ends of the ribs abutting against the abutting shoulders at the lower ends of the grooves, and means for locking one set of external segments to the core, substantially as described.

4. A grinding or crushing head comprising a central core having a number of dovetailed grooves extending from the top to a point near the bottom each having an abutting shoulder at its lower end, a set of external segments, made wider at the bottom than at the top, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves in the core, and another set of external segments, made wider at the top than at the bottom, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves of the core, the several segments of said sets being alternately disposed about the core and abutting together, and the lower ends of the ribs abutting against the abutting shoulders at the lower ends of the grooves, and transversely-disposed keys interspersed between the segments and core for locking said segments to the core, substantially as described.

5. A grinding or crushing head comprising a central core having a number of dovetailed grooves extending from the top to a point near the bottom each having an abutting shoulder at its lower end, a set of external segments, made wider at the bottom than at the top, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves in the core, and another set of external segments, made wider at the top than at the bottom, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves of the core, the several segments of said sets being alternately disposed about the core and abutting together, and the lower ends of the ribs abutting against the abutting shoulders at the lower ends of the grooves, transversely-disposed keys interspersed between the segments and core for locking said segments to the core, and means for holding said keys in place, substantially as described.

6. A grinding or crushing head comprising a central core having a number of dovetailed grooves extending from the top to a point near the bottom each having an abutting shoulder at its lower end, key-receiving recesses crossing alternate grooves provided with entrance thereto, a set of external segments, made wider at the bottom than at the top, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves of the core, and another set of external segments, made wider at the top than at the bottom, placed on said core and also having longitudinal dovetailed ribs fitting the dovetailed grooves of the core, the several segments of said sets being alternately disposed about the core and abutting together, and the lower ends of the ribs abutting against the abutting shoulders at the lower ends of the grooves, and transversely-disposed keys contained in said key-receiving recesses, substantially as described.

7. A grinding or crushing head comprising a central core having a number of dovetailed grooves extending from the top to a point near the bottom each having an abutting shoulder at its lower end, key-receiving recesses crossing alternate grooves provided with entrance thereto, a set of external segments, made wider at the bottom than at the top, placed on said core and having longitudinal dovetailed ribs fitting the dovetailed grooves of the core, and another set of external segments, made wider at the top than at the bottom, placed on said core and also having longitudinal dovetailed ribs fitting the dovetailed grooves of the core, the several segments of said sets being alternately disposed about the core and abutting together, and the lower ends of the ribs abutting against the abutting shoulders at the lower ends of the grooves, transversely-disposed keys contained in said key-receiving recesses, and means for closing the entrance to said key-receiving recesses and for locking the keys in place, substantially as described.

700,527. DOOR-SECURE. DANIEL J. HATHORN, Hingham, Mass. Filed Feb. 27, 1902. Serial No. 55,595. (No model.)

Claim.—A door-latch comprising an anchor-plate and a latched stop, the anchor-plate being provided with a gauge-plate struck up therefrom and the stop with a finger to engage said gauge-plate and to hold the stop in a horizontal position, substantially as set forth.

700,528. BREATHER WITH NASAL ATTACHMENT. GEORGE H. MAHER, Washington, D. C. Filed Nov. 4, 1901. Serial No. 51,525. (No model.)

Claim.—In an inhaler or respirator, the combination with the nose-spring and pad-carrying frame, of the interposed pads secured in said pad-carrying frame upon their inner faces near the rear portion of said pad-carrying frame, an open pocket of textile fabric secured to said nose-spring and to said pad-carrying frame and extending below the entrance to the nostrils of the wearer; and an absorbent material adapted to receive a curative medicament and to permit of inhalations and exhalations of the latter without permitting the medicament absorbent material to enter and obstruct the entrance of the nostrils; substantially as specified.

700,529. FLUXING AND SEPARATING COMPOUND. ABRAHAM D. MILLER, Mount Pleasant, Pa. Filed Mar. 12, 1901. Serial No. 52,905. (No specimen.)

Claim.—1. A fluxing and separating compound consisting of asbestos and a flux.
2. A fluxing and separating compound consisting of asbestos and borax.
3. A fluxing and separating compound consisting of asbestos, a flux, and an oxygen-furnishing agent.
4. A fluxing and separating compound consisting of asbestos, borax, and an oxygen-furnishing agent.
5. A fluxing and separating compound consisting of asbestos, borax, and potassium permanganate.
6. A fluxing and separating compound consisting of asbestos, a flux, and potassium permanganate.

700,530. PROCESS OF TREATING ORS. ABRAHAM D. MILLER, Mount Pleasant, Pa. Filed Mar. 12, 1901. Serial No. 51,508. (No specimen.)

Claim.—1. That process for the treatment of ors which consists in mixing the ore with asbestos and a flux and in subjecting the ore thus treated to the action of heat.
2. That process for the treatment of ore which consists in mixing the ore with asbestos and a flux and in subjecting the ore thus treated to the action of an oxygen-furnishing agent and heat.
3. That process for the treatment of ore which consists in mixing the ore with asbestos and a flux, and in subjecting the ore thus treated to the action of heat in the presence of oxygen furnished both mechanically and by chemical reaction.
4. That process for the treatment of ore which consists in mixing the ore with asbestos, a flux and potassium permanganate of potash, and in subjecting the ore thus treated to the action of heat.

700,531. COOLING AND AIRATING DEVICE. JOHN C. MILLER, Canton, Ohio. Filed Apr. 26, 1901. Serial No. 57,525. (No model.)

Claim.—A mill-cooler comprising a frusto-conical wall, an inverted flared top forming a slightly-inclined and comparatively broad supporting and mill-distributing surface, a frusto-conical spirally-stopped partition upon the interior of said vessel and forming a serpentine passage for the circulation of a cooling liquid, an inverted flared partition closing the top of the said partition and forming with the top of the cooling vessel a shallow passage communicating on all sides with said serpentine passage and also forming a comparatively broad and slightly-inclined plane surface for the flow thereover of the cooling liquid, a tube for supplying the cooling medium to the lower end of the spiral passage, a discharge-tube connecting said shallow passage with the interior of the partition, a mill-receiver having a discharge-orifice, a stationary cone upon the top of the cooling vessel and projecting into said orifice, supports between the receiver and top of the cooling vessel, and turnbuckles carried by said supports for adjusting the receiver up and down to vary the position of the cone within said orifice, substantially in the manner set forth.

700,582. POWER-TRANSMITTER. SAMUEL MILLER, New York. N. Y. Filed Mar. 5, 1908. Serial No. 98,535. (No model.)

Claim.—1. A power-transmitter comprising a driving-disk, a driven disk, a transmitter-shaft provided with movable bearings, friction-wheels on said shaft, a wedge-faced block connected to and movable with said shaft, a cam adapted to cooperate with the wedge-faced block, and means for moving the cam whereby the transmitter-shaft is moved laterally and the friction-wheels brought into contact with the driving and driven disks, substantially as described.

2. A power-transmitter comprising a driving-disk, a driven disk, a transmitter-shaft provided with movable bearings, friction-wheels on said shaft, a wedge-faced block connected to and movable with said shaft, a cam adapted to cooperate with the wedge-faced block, a friction device connected to and operating with said cam, and means for moving the cam whereby the transmitter-shaft is moved laterally and the friction-wheels brought into contact with the driving and driven disks substantially as described.

3. A power-transmitter comprising a driving-disk, a driven disk, a transmitter-shaft provided with movable bearings, a U-shaped frame pro-

vided with forked or Y-shaped ends, within which the said bearings move, friction-wheels on said shaft, a wedge-faced block connected to and movable with said shaft, a cam adapted to cooperate with the wedge-faced block, and means for moving the cam whereby the transmitter-shaft is moved laterally and the friction-wheels brought into contact with the driving and driven disks substantially as described.

4. A power-transmitter comprising a driving-disk, a driven disk, a transmitter-shaft provided with movable bearings, a U-shaped frame provided with forked or Y-shaped ends, within which the said bearings move, friction-wheels on said shaft, a wedge-faced block connected to and movable with said shaft, a cam adapted to cooperate with the wedge-faced block, a friction device connected to and operating with said cam, and means for moving the cam whereby the transmitter-shaft is moved laterally and the friction-wheels brought into contact with the driving and driven disks substantially as described.

5. A power-transmitter comprising a driving-disk, a driven disk, a transmitter-shaft provided with movable bearings, friction-wheels on said shaft, a wedge-faced block connected to and movable with said shaft, a cam adapted to cooperate with the wedge-faced block, a cam connected to said cam and provided with a brake apparatus adapted to cooperate with the driven disk, and means for moving the cam and brake whereby the transmitter-shaft is moved laterally and the friction-wheels brought into contact with the driving and driven disks and the brake withdrawn, substantially as described.

6. A power-transmitter located entirely below the work-table, comprising a driving-disk, a driven disk, a transmitter-shaft provided with movable bearings, friction-wheels on said shaft, a wedge-faced block connected to and movable with said shaft, a cam adapted to cooperate with the wedge-faced block, a braking device connected to and operating with said cam, means for moving the cam whereby the transmitter-shaft is shifted laterally and the friction-wheels brought into contact with the driving and driven disks, and means connecting the driven disk with a sewing-machine, substantially as described.

7. A power-transmitter located entirely below the work-table, comprising a driving-disk, a driven disk, a transmitter-shaft provided with movable bearings, a U-shaped frame provided with forked or Y-shaped ends, within which the said bearings move, friction-wheels on said shaft, a wedge-faced block connected to and movable with said shaft, a cam adapted to cooperate with the wedge-faced block, means for moving the cam whereby the transmitter-shaft is shifted and the friction-wheels brought into contact with the driving and driven disks, and means connecting the driven disk with the sewing-machine, substantially as described.

8. A power-transmitter comprising a driving-disk, a driven disk, a transmitter-shaft provided with movable bearings, a U-shaped frame provided with forked or Y-shaped ends, within which the said bearings move, friction-wheels on said shaft, a wedge-faced block connected to and movable with said shaft, a cam adapted to cooperate with the wedge-faced block, a rod connected to said cam and provided with a brake apparatus adapted to cooperate with the driven disk, and means for moving the cam and brake whereby the transmitter-shaft is moved laterally and the friction-wheels brought into contact with the driving and driven disks and the brake withdrawn, substantially as described.

700,588. FERTILIZER-DISTRIBUTOR. WILLIAM F. HARR, Mass. Tol. Filed June 1, 1901. Serial No. 68,732. (No model.)

Claim.—In a fertilizer-distributor, the combination with a wheeled truck; of a hopper for the fertilizing material, said hopper being supported on the truck-frame, a conical trough forming the bottom of the hopper and provided with a series of discharge-openings extending transversely of the machine, an agitator-shaft within the trough, means for driving said shaft, and a cut-off or head comprising disks which slope transversely of the machine and are provided on their lower edges with vertical slots removably fitted in the central portion of the hopper over the agitator-shaft whereby the centrally-arranged discharge-openings are covered and the fertilizer directed toward the end openings.

700,584. GRANULATING ATTACHMENT FOR SALT-SHAKERS. JAMES A. MILLER, JR., New York, N. Y. Filed Feb. 26, 1908. Serial No. 98,716. (No model.)

Claim.—1. In a sub-chamber, a cap having an attached agitator on a shaft of spring-wire, the wire being bent upon itself to form intermediate downwardly-extending members crossing one another with an open twist, and upwardly-extending side members, as and for the purpose set forth.

2. In a sub-chamber, a cap and an agitator attached to the under face of the cap, said agitator being constructed of spring-wire of suitable gage bent upon itself to form an upper loop, and intermediate members extending downward from the ends of the loop, crossing one another with an open twist, and side members carried up from the lower ends of the intermediate members to a point opposite the twist, the upper ends of the side members having an inward curve, as and for the purpose specified.

3. As an improved article of construction, an agitator for the caps of sub-chambers and similar vessels, consisting of a piece of spring-wire of suitable gage bent upon itself to form an upper loop member, intermediate members extending downwardly from the ends of the loop member crossing each other with an open twist, and side members extending from the lower ends of the intermediate members to a point near the twist, the side members being opposite each other and having their upper ends inwardly and upwardly curved, as and for the purpose set forth.

4. The combination with a cap for a sub-chamber or similar vessel, of an agitator constructed of spring-wire and comprising an upper loop member, intermediate members extending downwardly from the ends of the loop member, crossing one another with an open twist, and upwardly-extending side members having their upper extremities inwardly curved, and a plate for attaching the agitator to the cap, which plate is provided with a central channel receiving the loop member of the agitator, and with apertures adjacent to said channel, for the purpose described.

700,585. GAS-HEATER. EDWARD A. MARR, Elizabeth, N. J. Filed Apr. 11, 1901. Serial No. 68,594. (No model.)

Claim.—1. In a gas-heater, the combination of an hollow gas-pipe, an open-bottom hollow cylinder surrounding the same, a removable cover on this cylinder having a central nozzle and side perforations, and a conical open-bottom hollow cylinder, of larger diameter partly surrounding and extending above the first, and a reticulated-diaphragm burner at the top of this cylinder.

2. In a gas-heater, the lower cylinder open at bottom and having supporting-legs, brackets extending outward from the side of said cylinder, the upper larger cylinder removably supported on said brackets and extending the upper portion only of the lower cylinder, and a removable reticulated diaphragm and flanged ring fitting the top of said upper cylinder, substantially as described.

3. In a gas-heater, the combination of the cylindrical mixing-chamber, a reticulated diaphragm at the top thereof and a flanged ring retaining the same, and a separately-removable metallic deflector-plate sup-

ported above said diaphragm by legs connected to the plate and resting on the flange-ring, substantially as described.

4. In a gas-heater, the combination of the cylindrical mixing-chamber, a reticulated diaphragm held by a removable flanged ring at the top thereof, an auxiliary reticulated ring-burner above the diaphragm, with open gas-passages below, and a cover above said auxiliary ring-burner, substantially as described.

5. In a gas-heater, the combination of the mixing-chamber, a reticulated diaphragm at the top thereof, a ring-burner of reticulated material above said diaphragm and having an outwardly-turned flange at its lower edge and a space below the same, and a cover for said ring-burner.

6. In a gas-heater as described, the combination with the mixing-chamber having a reticulated diaphragm at the top, of a ring-burner of reticulated material supported above the diaphragm, having a space between, a flange extending outwardly from the base of said ring-burner, and a cover for said ring-burner, as set forth.

7. In a gas-heater, the combination with the mixing-chamber having a reticulated diaphragm at the top, of a ring-burner of reticulated material and having legs by which the same may be removably supported from the chamber, leaving an open gas-passages below said ring, and a cover for said ring-burner.

8. In a gas-heater, the combination with the mixing-chamber having a reticulated burner, of an auxiliary ring-burner of reticulated material supported above said diaphragm, and a separately-removable deflector-plate above said ring-burner.

9. In combination with the mixing-chamber and reticulated diaphragm at the top, a separately-removable deflector-plate of sheet metal having notched edges and supporting-legs to rest on the top of said chamber.

700,586. APPARATUS FOR DEMONSTRATING THE PHENOMENA OF ELECTRICITY. EDWARD J. MARR, and DAVID G. MARR, Graham, Pa. Filed Nov. 22, 1901. Serial No. 68,968. (No model.)

Claim.—1. In an apparatus of the class set forth, the combination of frictional electrical generating devices, Leyden jars provided with upwardly-extending adjustable insulated rods and having contact devices engaging the inner linings thereof, transmitting attachments between the rods and the frictional generating devices, a disk held in suspended relation to one of the said rods, and an object supported by the other rod under the said disk.

2. In an apparatus of the class set forth, the combination of electrical generating means, accumulators having transmitting devices therefor in operative proximity to portions of said generating means, connecting devices extending upwardly from said accumulators, a casing inclosing the apparatus and having a removable slide with contact-strips thereon, a switch-bar for connecting said contact-strips and operative from the exterior of the casing, resilient conductors in the bottom of the casing having the opposite terminals respectively in contact with said strips and with devices extending downwardly from the bottom portions of the accumulators, a disk held in suspended relation to one of the accumulators, and an object supported by a portion of the other accumulator and located under the disk.

3. In an apparatus of the class set forth, the combination of static electrical generating devices, one part of which has accumulators thereon, exteriorly-adjustable equalizing-combs, Leyden jars having transmitting devices in operative proximity to the generating devices, a disk adjustably supported by a portion of one of the Leyden jars, and an object adjustably supported by the other Leyden jar under said disk.

4. In an apparatus of the class set forth, the combination of static electrical generating device, Leyden jars having translating attachments in operative proximity to the said generating device, conductors adjustably extending upwardly from the Leyden jar and having upper terminal heads, electrodes slidable through and rotatable with the said heads, a disk suspended by one head, and an object held by the opposite head under the disk.

5. In an apparatus of the class set forth, the combination of static electrical generating device, a pair of Leyden jars having translating devices in operative proximity to said generating device, insulating-tubes extending upwardly from the top portions of the said jars, conducting-rods adjustable in the said tubes and having heads at their upper ends, the said rods being rotatable, electrodes horizontally disposed and slidably mounted in the said heads, and devices supported by the said heads in such relation that an electrical spark will be caused to pass from one to the other.

6. In an apparatus of the class set forth, the combination with static electrical generating and storage device, of members projecting upwardly from the said storage device, an upright held by one of said members, a weighted balance-arm suspended in the upper portion of said upright, a dial held by one end of the balance-arm, a metal plate mounted on the other member, and an object disposed on the metal plate under the said dial and having a conductor in the upper portion thereof.

700,587. APPARATUS FOR GENERATING SULFUR DIOXIDE
JOHN D. MOORE, NEW YORK, and FRED M. HANSEN, BROOKLYN, N. Y.; said Moore assignor to the Clayton Fire Extinguishing & Dismantling Company, a Corporation of West Virginia. Filed May 22, 1891. Serial No. 81,348. (No model.)

Claim.—1. In an apparatus for generating sulfur-dioxide gas, the combination with a generator in which the gas is produced by the action of air on a suitable substance in a heated state, of a system of outgoing and intake pipes, a valve in the intake-pipe for controlling the passage through the same, and a second valve, in operative connection therewith, for simultaneously controlling the admission of outside air into the intake, and a pump connected with the system of pipes, as set forth.

2. In an apparatus for generating sulfur-dioxide gas, the combination with a generator in which the gas is produced by the action of air on a suitable substance in a heated state, of outgoing and intake pipes connected by a pipe or passage forming a by-pass, a valve mechanism for simultaneously controlling the passage through the intake-pipe and the admission of outside air thereto, and a second valve mechanism for simultaneously controlling the passage through the outgoing pipe and the by-pass connection of the intake-pipe therewith, as set forth.

3. In an apparatus for generating sulfur-dioxide gas, the combination with a generator of the kind described, outgoing and intake pipes, a by-pass connection between the same, a valve adapted to simultaneously

close the inlet and outlet of the generator and open communication through the by-pass, a cooling device in the circuit of said pipes, and means for maintaining a circulation of gas through the same, as set forth.

4. In an apparatus for generating sulfur-dioxide gas, the combination with a generator consisting of a receptacle for containing the substance to be burned, and having inlet and outlet pipes for the circulation of air and gas through the same, the receptacle being surrounded and protected by an adiabatic covering to prevent the radiation of heat, a by-pass connection between the inlet and outlet pipes, and means for maintaining a circulation of gas through the circuit of said pipes, as set forth.

700,588. METHOD OF CHARGING COMPARTEMENTS WITH GAS
JOHN D. MOORE, NEW YORK, and FRED M. HANSEN, BROOKLYN, N. Y.; said Moore assignor to the Clayton Fire Extinguishing & Dismantling Company, a Corporation of West Virginia. Filed May 22, 1891. Serial No. 81,348. (No model.)

Claim.—1. The method of rapidly producing in closed compartments an atmosphere of sulfur-dioxide gas for fire-extinguishing or disinfectant purposes, which consists in heating the gas-producing substance in a suitable generator, bringing into union with the gas and sulfur vapor issuing from the generator, and while still in a highly-heated state, a sufficient proportion of atmospheric air to convert the uncombined sulfur into gas, and forcing the resulting gas through the system of piping which conveys it to the compartment, as set forth.

2. The method of rapidly producing in closed compartments an atmosphere of sulfur-dioxide gas for fire-extinguishing or disinfectant purposes, which consists in heating a gas-producing substance in a suitable generator, forcing air through the generator and bringing into union with the gas and vapor issuing therefrom, and while still in a highly-heated state, an additional quantity of outside air, sufficient only in amount to convert the uncombined sulfur into gas, cooling the resulting gases and conveying them to the compartment, as set forth.

700,589. ADJUSTABLE SLIDE-POKE HARRY C. MORAS, NEWTON, MASS. Filed Dec. 6, 1891. Serial No. 84,772. (No model.)

Claim.—1. A tubular slide-form composed of a plurality of tapering longitudinal sections collectively forming a longitudinally-divided arm-shaped tube, each section being externally convex in cross-section the radii

of cross-sectional curvature gradually increasing from its lower to its upper end, and adjustable connections between said sections whereby the diameter of the tube may be varied.

2. A tubular slide-form composed of a plurality of tapering longitudinal sections collectively forming a longitudinally-divided arm-shaped tube, each section being externally convex in cross-section, the radii of cross-sectional curvature gradually increasing from its lower to its upper end and a plurality of sets of adjustable connections between said sections, whereby the diameter of the tube may be varied at either end portion.

3. A tubular slide-form composed of a plurality of longitudinal sections collectively forming a longitudinally-divided arm-shaped tube, inwardly-projecting slotted arms affixed to said sections and having their inner ends overlapped, and clamps engaged with the overlapped ends of said arms within the tube.

700,540. ATTACHMENT FOR CORE-PLANTER JAMES R. HULDER, RANDELVILLE, IND. Filed Dec. 6, 1891. Serial No. 84,948. (No model.)

Claim.—1. In a planter of the class set forth, the combination with a seed box or hopper provided with valve mechanism, of a fork disposed in advance of said valve mechanism and pivoted at an intermediate point, a spring attached to the fork to return it to normal position, a bolt movable through the fork and provided with a vertically-disposed tappet having a length greater than the distance between the members of the fork and adapted to slide over side edge portions of the fork and off the ends of the latter, and mechanism for actuating the said bolt.

2. In a planter of the class set forth, the combination with a seed-box having valve mechanism, of a horizontally-disposed reciprocating fork pivoted at an intermediate point and connected to said valve mechanism, the bifurcated extremity of the fork being projected outwardly and elevated above the plane of the device for holding it, a spring attached to the lower extremity of the fork to return the same to normal position, a bolt movable through the bifurcated extremity of the fork and provided with a vertically-disposed tappet which engages the side edge portions of the bifurcated extremity of the fork and moves over and around the ends of said extremity, the said bolt being located outside of the adjacent portion of the machine and the tappet of greater vertical extent than that of the bifurcated extremity of said fork, and mechanism connected to the carrying-wheel of the machine for actuating the said bolt.

700,541. FLOW ATTACHMENT HERMAN E. HANSON, DETROIT, MICH. assignor to the Waukegan Flow Company, St. Clair, Mich. Filed Aug. 21, 1891. Serial No. 78,971. (No model.)

Claim.—1. The combination with a plow, of a hanger-bar carrying a wheel mounted on one side of the plow-beam, a second hanger-bar provided with a grooved horizontal web mounted on the opposite side of the plow-beam, on axle, carrying a wheel, engaging the groove in said horizontal web, means for adjusting said axle laterally in said groove, and means for clamping said hanger-bars to the plow-beam.

2. The combination with a plow, of a pair of clamps located on each side of the plow-beam, a pair of hanger-bars secured between said clamps and plow-beam, one of said hanger-bars having an axle formed integral therewith for carrying a wheel, the other said hanger-bar provided with a grooved horizontal web provided with bolt-holes, a perforated axle, carrying a wheel, engaging said groove, the perforations in said axle adapted to align with the bolt-holes in said horizontal web for securing the lateral adjustment of said axle.

3. The combination with a plow of a pair of perforated hanger-bars carrying wheels located on each side of the plow-beam, clamps having lugs engaging in said perforations, and tie-bolts for tying said clamps and axle-hangers together on the plow-beam.

4. The combination with a plow of a pair of hanger-bars carrying wheels located on each side of the plow-beam, clamps engaging said hanger-bars, tie-bolts mounted above and beneath the plow-beam and engaging said clamps, and a wedge adapted to be inserted between said upper tie-bolt and plow-beam for securely attaching the said hanger-bars to the plow-beam.

5. The combination with a plow, of a pair of hanger-bars carrying axles and wheels located on each side of the plow-beam, clamps engaging said hanger-bars, tie-bolts mounted above and beneath the plow-beam and engaging said clamps, and a corrugated wedge adapted to be inserted between said upper tie-bolt and plow-beam for securely attaching the said hanger-bars to the plow-beam, substantially as described.

700,542. LADDER JAMES C. MCCORMACK, MAINE, assignor of two-thirds to WILLIAM E. JACOBS and WILLIAM E. ROBERTSON, MAINE. Filed June 15, 1891. Serial No. 84,573. (No model.)

Claim.—1. A folding fire-escape ladder comprising side bars, connecting-rungs, the side bars being composed of sections which are hinged or jointed to the rungs, and are provided with stop-shoulders arranged to abut together and hold the sections in angular relation to each other when the ladder is extended, and flexible, inextensible cords attached to and extending between the alternate hinge-joints of the side bars, said cords cooperating with the stop-shoulders in maintaining the angular relation of the sections.

2. A folding fire-escape ladder comprising side bars each composed of sections having hinge-shoulders and stop-shoulders at their ends, rungs extending between said bars their ends constituting hinge-plate members engaged with said hinge-shoulders, said stop-shoulders being arranged to abut together when the ladder is extended and hold the side-bar sections in angular relation to each other, whereby outer and inner angles are provided, the inner angles being adapted to bear against the wall of a building and hold the outer angles and the rungs connected therewith at a distance from said wall, and flexible inextensible cords affixed to and extending between the plate members of the outer angles, said cords cooperating with the stop-shoulders in maintaining the angular relation of the side-bar sections.

700,548. FIRE-ESCAPE. JAMES C. McFARLAN, Malden, Mass., assignor of TWO-THIRDS to WILLIAM S. JONES and WILLIAM H. McFARLAN, Malden, Mass. Filed Oct. 12, 1891. Serial No. 79,978. (No model.)

Claim.—1. In a fire-escape, a ladder-support consisting of a bar having arms adapted to extend through a window-opening in a building-wall and formed to engage the inner side of the wall, the said arms supporting the bar in a horizontal position outside the window-opening, a ladder-engaging arm hinged at one end to said bar at a point between the ends of the latter and adapted to swing horizontally to one side of the window-opening to extend the arm and locate the ladder out of the line of a lower window or series of windows, and supporting members on the arm and bar, arranged to support the arm between its hinged and swinging ends when the arm is extended.

2. In a fire-escape, a ladder-support comprising a bar having arms adapted to extend through a window-opening in a building-wall and formed to engage the inner side of the wall and support the bar horizontally outside the opening and a ladder-engaging arm hinged at one end to the bar at a point between the ends of the latter and adapted to be extended by a horizontal swinging movement to one side of the window and arm having a downwardly-projecting foot between its hinged and swinging ends, while the bar has a cast which supports said foot when the arm is extended, said cast and foot having interlocking members which prevent the base swinging of the extended arm.

3. In a fire-escape, a ladder-support comprising a bar having arms adapted to extend through a window-opening in a building-wall and formed to engage the inner side of the wall and support the bar horizontally outside the opening, and a ladder-engaging arm hinged at one end to the bar at a point between the ends of the latter and adapted to be extended by a horizontal swinging movement to one side of the window, said arm having a downwardly-projecting foot at its swinging end and while the bar has a cast arranged to engage said foot when the arm is not extended.

4. In a fire-escape the combination of a ladder-support comprising a bar having arms adapted to extend through a window-opening in a building-wall and formed to engage the inner side of the wall and support the bar horizontally outside the opening, and a ladder-engaging arm hinged at one end to the bar at a point between the ends of the latter and adapted to be extended by a horizontal swinging movement to one side of the window, a ladder suspended from said arm, and one or more ladder rungs or steps suspended from said bar, said rungs or steps enabling a person to reach the ladder on the extended arm substantially as described.

700,544. METHOD OF CONNECTION OF CURRENT-COLLECTING OR TROLLEY POLES. PHILIP McFARLAN, THOMAS BLUNT, and BENJAMIN BARON, Liverpool, England; said BLUNT and BARON assignors to said McFARLAN. Filed Jan. 14, 1892. Serial No. 80,042. (No model.)

Claim.—1. In an electric-current-collecting or trolley pole, the combination with a headpiece, of a pole connected therewith, a conductor secured and insulated in said headpiece, a plate attached to said conductor, and a second plate facing the first plate and contacting therewith through a plurality of bearing-balls.

2. In an electric-current-collecting or trolley pole, the combination with a standard, of a headpiece to which the pole is connected, a cap on the top of the standard, bearings for the headpiece in said cap, a conducting-rod secured and insulated in said headpiece, an insulated conductor connected to said conducting-rod and to the current-collector on the end of the pole, a plate on the lower end of the conducting-rod, a second plate

opposite the first and rigidly mounted and insulated in the standard, balls between said plates, and a conductor for carrying away the current from the said second plate.

3. In an electric-current-collecting or trolley pole, the combination of a reversible headpiece to which the pole is attached, a conducting-rod mounted in insulation in said headpiece, and electrically connected to the current-collector, a plate attached to said conducting-rod, a second plate facing said first plate and fixed in insulation in the standard, and balls between said plates, whereby electric contact is established between them, and in whatever position the head may be said contact is kept constant.

4. The combination of the headpiece of the pole of which the pole is attached, a conducting-rod mounted in insulation in said headpiece, a plate attached to said conducting-rod, a plate mounted in insulation in the standard, and balls between said plates, whereby the current from the collector is conveyed to the working parts of the vehicle in whatever position the head may be.

700,545. CORNER CHAIR AND CRADLE. ARTHUR HANSEN, Flushing, Mass. Filed Mar. 7, 1892. Serial No. 80,126. (No model.)

Claim.—1. In a cradle, the combination with a rocking-chair having a back and seat, of frames hinged to the sides of said back, frames hinged to the sides and the front of said bottom, frames hinged to the sides of the said bottom hinged to the sides of said bottom, and means for connecting said frames together to form a cradle-bar, substantially as described.

2. In a cradle, the combination with a rocking-chair having a back and seat, of a pair of frames one hinged to each side of said back and adapted to extend in the plane thereof or to be folded back in contact therewith, a pair of frames one hinged to each side of said bottom, said frames being adapted to extend in the plane of said bottom or to stand at right angles thereto to form same, a pair of frames hinged to the sides of said last-mentioned frames and adapted to form the ends of the cradle or to be folded down in contact with said frames, a frame hinged to the front of said bottom and adapted to stand up at right angles thereto or to be folded down in contact therewith, and a pair of frames hinged to the opposite sides of said last-mentioned frame and adapted to extend in the plane thereof or to be folded up in contact therewith and means for securing said frames together, substantially as described.

700,546. WATER-HEATER AND STEAM-GENERATOR. CHAS. HALLMAN, Cranford, N. J. Filed Jan. 3, 1892. Serial No. 80,214. (No model.)

Claim.—1. A boiler provided with a fastening-roll, a driving or main axle, axle driven by the main axle and having a bearing in the fastening-roll, and water-impelling device carried by the driven axle.

2. A boiler provided with a fastening-roll and pillow-block, a driving or main axle extended longitudinally through the boiler, axle placed transversely to and driven by the main axle and supported in said fastening-roll and pillow-block, water-impelling device on said transverse axle, and driving gears and shaft for the main axle, said boiler having a stuffing-box chamber for the passage of said last-mentioned shaft.

700,547. RANGE-FINDER. JOHN WILSON, Larchmont, N. Y. Filed Jan. 24, 1892. Serial No. 80,252. (No model.)

Claim.—1. A range-finder comprising a base, a telescope rigidly attached thereto, a telescope mounted thereon at an angle to said first-mentioned telescope, means of moving the second-mentioned telescope toward and away from the one first mentioned and of simultaneously adjusting the focal distance between the eyepieces of the first-mentioned telescope and the object-glass of the other one as the distance between the two telescopes is changed, means of throwing the rays received through the movable telescope into the fixed telescope and a scale to record the distance between the two telescopes and thereby that of the object viewed.

2. A range-finder comprising a base, a telescope rigidly attached thereto, a telescope mounted thereon at an angle to said first-mentioned telescope, means of adjusting said angle, means of moving the second mentioned telescope toward and away from the one first mentioned and of simultaneously adjusting the focal distance between the eyepieces of the first-mentioned telescope and the object-glass of the other one as the distance between the two telescopes is changed, adjustable means of throwing the rays received through the movable telescope into the fixed telescope and a scale to record the distance between the two telescopes and thereby that of the object viewed.

3. In a range-finder the combination of a base with a telescope rigidly attached thereto, a telescope mounted thereon at an angle to said first-mentioned telescope, means of moving the second-mentioned telescope toward and away from the one first mentioned and of simultaneously adjusting the focal distance between the eyepieces of the first-mentioned telescope and the object-glass of the other one as the distance between the two telescopes is changed, a prism adapted to divert the rays re-

ceived through the movable telescope toward the fixed telescope, a prism adapted to divert the rays received through the first-mentioned prism to the eyepiece of the right telescope, adjustable tubes connecting the first-mentioned prism both with the movable telescope and the other prism, and a scale to record the distance between the two telescopes and thereby that of the object viewed.

700,548. CORNER-SUPPORT FOR PICTURE-FRAMES. JOHN T. HANSEN, New York, N. Y. Filed Jan. 11, 1892. Serial No. 80,253. (No model.)

Claim.—1. The combination with a picture and a transparent covering therefor, of corner-supports having adjustable eyes projecting outwardly therefrom, a flexible supporting element threaded through the said eyes and surrounding the picture and covering, and a hanger secured to said flexible device.

2. The combination with a picture and a transparent covering therefor, of corner-supports and fasteners comprising bodies with pairs of inwardly bent hooks on adjacent edges and adjustable eyes interconnecting the said hooks, a chain threaded through the said eyes and surrounding the picture and covering, and a hanger attached to the upper part of the said chain.

700,549. BLAST-FURNACE. FRANK C. HODGSON and JAMES MITCHELL, Lorain, Ohio. Filed Feb. 15, 1892. Serial No. 80,256. (No model.)

Claim.—In combination with a blast-furnace, a dust-collecting pipe, a series of injecting-pipes inserted through the walls of the furnace, at intervals from top to bottom, and connected transversely with said dust-pipe, and means, substantially as described, connected to said injecting-pipes for forcibly injecting the dust into the furnace, substantially as and for the purpose set forth.

700,550. MUSIC-BOX. GEORGE OTTO and FREDERICK SCHMIDT, Jersey City, N. J. Filed Jan. 14, 1891. Serial No. 80,260. (No model.)

Claim.—1. In a mold-box, the combination with a casing, of a wood casing-board secured at its edge to the casing, a metal base-plate secured directly on said casing-board, a metallic comb on said base-plate, and means for picking the teeth of the comb, substantially as herein shown and described.

2. The combination with a casing, of a casing-board secured at its edge to the casing, a metal base-plate secured directly on the casing-board, a metallic comb on said base-plate, means for picking the teeth of the comb, and a auto-disk-operating gear secured to the casing entirely independent of the casing-board and base-plate, substantially as herein shown and described.

3. The combination with a casing, of a wood casing-board secured at its edge to the casing, a metal base-plate secured directly on the casing-board, a metallic comb on said base-plate, means for picking the teeth of the comb, a motor secured to the casing entirely independent of the casing-board and base-plate, a disk-rotating gear operated from said motor, the base-plate and casing-board having slots through which said driving-gear extends, substantially as herein shown and described.

700,551. MACHINE FOR MOLDING ARTIFICIAL STONE.
JOHN F. PALMER, Brooklyn, N. Y. Filed Feb. 14, 1902. Serial No. 94,012. (No model.)

Claim.—1. In a machine for molding artificial stone, the combination of a mold-box having sliding sides and ends, with a series of inter-gearing shafts corresponding in number to the number of mold-box sides and ends, and with racks and pinions for transmitting motion from the shafts to said sides and ends, substantially as specified.

2. In a machine for molding artificial stone, the combination of a mold-box having sliding sides and ends, with a series of inter-gearing shafts arranged concentric to the mold-box, pinions mounted upon said shafts, racks engaged by the pinions, and means for connecting said racks to the sliding sides and ends, substantially as specified.

3. In a machine for molding artificial stone, the combination of a rectangular mold-box having sliding sides and ends, with four inter-gearing shafts arranged in a rectangle concentric to said mold-box, pinions mounted upon said shafts, two series of racks engaged by said pinions and extending at right angles to each other, and means for connecting said racks to the sliding sides and ends, substantially as specified.

700,552. CUTTER-HEAD BIT. EMERY A. PARSON and BLAKE S. SHIMES, Milton, Pa., assignors to Samuel J. Shimer and Sam. Milton, Pa. Filed Feb. 21, 1902. Serial No. 92,168. (No model.)

Claim.—1. A bit for cutter-heads comprising a body having a curved cutting edge and a heel formed on an embroken curve which is parallel to and a counterpart of the curve of the cutting edge, the curve of said heel being adapted to form a pattern by which to grind the said cutting edge, substantially as described.

2. A bit for cutter-heads comprising a cylindrical body having a curved cutting edge and a curved heel, the curve of said heel being parallel to the curve of said cutting edge and adapted to form a pattern for grinding the said cutting edge, substantially as described.

3. A cutter-head bit comprising a cylindrical body having a cutting edge conforming to a portion of the curve of intersection of the surfaces of two non-parallel intersecting cylinders and a heel formed on a curve parallel to the curve of said cutting edge, substantially as described.

700,553. PAPER-MAKING MACHINE. HOWARD PARKER, Bellevue Falls, Va. Filed Sept. 12, 1900. Serial No. 20,408. (No model.)

Claim.—1. In combination in a machine for paper-making machines, a series of links bearing plates and forming a carrier and motion apparatus operatively mounted with relation to said carrier and means for driving the carrier and maintaining a positive contact between its several sections as they pass over the motion apparatus, substantially as described.

2. The combination in paper-making machinery with the motion apparatus and the traveling forming-crown of a carrier interposed between the motion apparatus and the traveling crown, said carrier comprising links connected in pairs by perforated plates, substantially as described.

3. The combination in paper-making machinery with the motion apparatus and the traveling forming-crown of a carrier interposed between the motion apparatus and the forming-crown, said carrier comprising links connected in pairs by perforated plates, and means for controlling the openings between the plates as they pass over the motion apparatus.

ing the openings between the plates as they pass over the motion apparatus.

4. The combination in paper-making machinery with the motion apparatus and the traveling forming-crown of a carrier interposed between the motion apparatus and the traveling crown, said carrier comprising links connected in pairs by perforated plates, and a yielding material secured to the opening edges of said plates, as and for the purposes specified.

5. In combination in a device of the class specified, an endless carrier comprising a series of links and perforated plates, racks formed upon the links, gears for positively driving said links in a fixed relation to each other, and a motion-box operatively mounted with relation to said carrier, substantially as described.

6. In combination in a device of the class specified, an endless carrier comprising a series of links and perforated plates, racks formed upon the links, gears for positively driving said links in a fixed relation to each other, and a motion-box operatively mounted with relation to said carrier, and adapted to have a movement crosswise thereof.

700,554. PAPER-MAKING MACHINE. HOWARD PARKER, Bellevue Falls, Va. Filed June 12, 1901. Serial No. 65,142. (No model.)

Claim.—1. A motion apparatus for paper-making machines, and means for imparting a reciprocating motion to said motion apparatus.

2. The combination in paper-making machinery with the forming-crown and the motion apparatus located in operative relation thereto and a carrier-belt interposed between said crown and said motion apparatus, of means for causing a relative movement between the forming-crown and the motion apparatus in a direction transverse to the direction of movement of the forming-crown.

3. In a paper-making machine, the traveling forming-crown, and the motion apparatus located in operative relation thereto, and means for imparting a reciprocating motion to the motion apparatus in a direction transverse to the direction of movement of the forming-crown.

4. In a machine of the class specified, the forming-crown and motion apparatus arranged in operative relation thereto, said motion apparatus being made up of elements, and means for imparting a reciprocating movement to said elements in consecutive relation to each other.

5. In combination in a paper-making machine, a traveling forming-crown, a motion apparatus located in operative relation thereto and having a perforated top, and a perforated traveling carrier located between the forming-crown and the motion apparatus, substantially as described.

6. In combination, in a paper-making machine, the traveling forming-crown, the motion apparatus located in operative relation thereto and

having a perforated top, a perforated traveling carrier between the forming-crown and the motion apparatus, and means for causing a relative movement between the motion apparatus and the carrier, in a direction transverse to the direction of movement of the carrier.

7. In a machine of the class specified, the combination with the forming-crown and the motion apparatus, of a traveling belt located between the forming-crown and the motion apparatus, and a shifting device for automatically maintaining said belt in its proper position, substantially as described.

8. In a machine of the class specified, the combination with a frame supporting the motion apparatus, the motion apparatus located in said frame and the forming-crown, of a carrier-belt interposed between the motion apparatus and the forming-crown, and means for automatically controlling the position of the carrier-belt.

9. In a machine of the class specified, the combination with the frame supporting the motion apparatus, the motion apparatus located in said frame, and a forming-crown of an endless carrier-belt traveling over drums mounted on the frame, a roll mounted in yielding bearings in operative relation with one of the drums, and means for moving the bearings of said roll, substantially as described.

10. In a machine of the class specified, the combination with the frame supporting the motion apparatus, and the motion apparatus located in said frame, of an endless belt traveling over a drum mounted on the frame, a roll mounted in yielding bearings in operative relation with said drum, and means for moving the bearings of said roll, substantially as described.

700,555. PROCESS OF DETERMINING THE HEATING CAPACITY OF COMBUSTIBLES. SAMUEL W. PARK, Urbana, Ill. Filed Dec. 24, 1901. Serial No. 67,195. (No specimen.)

Claim.—1. The herein-described process of determining the heating capacity of combustibles, which consists in mixing sodium peroxide with the combustible in a closed vessel under ordinary atmospheric pressure, placing the vessel in a body of water, igniting the mixture, permitting a reaction of the mixture so that the ultimate products of the reaction will be solid substances, and taking the temperature of the water before and after the reaction.

2. The herein-described process of determining the heating capacity of combustibles, which consists in mixing together in a closed vessel the combustible, sodium peroxide, and other superoxidized substances which yield a maximum amount of oxygen, placing the vessel in a quantity of water, igniting the mixture, permitting a reaction of the mixture from said ignition so that the products thereof will be solid substances, and taking the temperature of the water before and after the reaction.

3. The process of determining the heating capacity of combustibles, which consists in mixing definite organic substances, as herein described, with sodium peroxide, and the combustible in a closed vessel, placing the vessel in a body of water, igniting the mixture, permitting a reaction of the mixture from said ignition, and taking the temperature of the water before and after the reaction.

4. The process of determining the heating capacity of combustibles in a closed vessel with definite organic substances, sodium peroxide, and

other superoxidized substances, placing the vessel in a body of water, igniting the mixture, permitting a reaction thereof from such ignition so that the products of the reaction will be solid substances, and taking the temperature of the water before and after the reaction.

700,556. CORSEY, ARTHUR E. PARKER, Boston, Mass. Filed Jan. 2, 1902. Serial No. 22,614. (No model.)

Claim.—A corset composed of two side sections or halves, each having continuous stiffening members at its front and rear edges extending from the upper to the lower end of the corset, a plurality of horizontal stiffening members arranged edge to edge and extending between said vertical members at the waist portion of the corset, flexible connections between the horizontal members, said horizontal members and connections constituting elongated hinges at the waist portion of the corset, two series of shorter vertical stiffening members extending from said hinges, one to the upper and the other to the lower end of the corset, and two series of metallic sockets attached to the body of the corset at opposite edges of said hinges, the series above the hinges being closed at their lower ends, while the series below the hinges are closed at their upper ends, one series of sockets opposing downward movement of the shorter vertical stiffening members above the hinges, while the other series of sockets oppose upward movement of the shorter vertical stiffening members below the hinges.

700,557. ROTARY ENGINE. THOMAS J. FERRIS, Koshconong, Mo. Filed Feb. 10, 1902. Serial No. 18,468. (No model.)

Claim.—1. In a rotary engine, the combination with a casing provided with admission and exhaust ports, and a shaft; of a piston comprising heads fixed to the shaft, a series of independent radial vanes extending between the heads and forming a series of radial pockets, a piston-disk loose upon the shaft to have axial play and disposed between the heads, said disk being formed with slots for the passage of the vanes, and means controlling the rotation of the disk in a plane at a diagonal angle to the plane of rotation of the shaft and heads, substantially as described.

2. In a rotary engine, a piston-disk provided with a central opening

and slots radiating therefrom, a shaft extending through the central opening, heads fixed to the shaft on opposite sides of the disk and having sockets in their inner faces, bearing-bases on the disk seated in said sockets, said bases having flaring bases allowing the piston to wobble on the shaft, radial vanes extending through the slots and between the heads and forming a series of radial pockets, a casing including the ports, and means controlling the rotation of the disk in a plane at a diagonal angle to the plane of rotation of the shaft and heads, substantially as and for the purposes described.

700,558. ANIMAL-PUMP. RICHARD H. FINNEY and DUNCAN A. JONES, New York, N.Y. Filed Jan. 27, 1902. Serial No. 91,000. (No model.)

Claim.—1. In an animal-pump, the combination with a curved metallic body-plate terminating at its forward end in integral upwardly-extending diverging arms, of a neckband adapted to be connected to the arm ends, a securing band or strap for the rear end of the plate, and a depending pole member pivoted to the plate for free swinging movement in a forward direction.

2. In an animal-pump, the combination with an oblong metallic plate curved about its longitudinal axis to conform to the exterior of the body of the animal, of diverging arms integral with the plate and extending upwardly from the forward end of the latter, a neckband connecting the arm ends, a securing-band for the rear portion of the plate, a vertically depending pole-bar having pivotal connections with the plate and provided with diverging prongs or arms, and a bearing-carriage formed on the inner end of said bar, substantially as and for the purposes set forth.

700,559. FIRE-LENS LAMP. EDWARD D. BROWNE, Bristol, Conn., assignor to the Liberty Bell Company, Bristol, Conn., a Corporation. Filed Oct. 7, 1901. Serial No. 77,804. (No model.)

Claim.—1. In a fire-lens lamp, in combination, a supporting-frame, a winding-cylinder mounted to turn therein, a drag or brake for restraining the turning of said cylinder, a single actuating device for turning said cylinder for producing the desired frictional contact between said drag or brake and winding-cylinder, and means for connecting and disconnecting said actuating device and winding-cylinder, substantially as described.

2. In a fire-lens lamp, in combination, a supporting-frame, a winding-cylinder mounted to turn therein, a drag or brake for restraining the turning of said cylinder, a crank or arm for turning said cylinder, a detachable connection between said crank or arm and said cylinder, said crank or arm arranged to apply the drag or brake when disconnected from the cylinder, substantially as described.

3. In a fire-lens lamp, in combination, a supporting-frame, a winding-cylinder mounted to turn therein, a crank or arm for turning said cylinder, a knob or handle carried by and arranged to turn in said crank or arm and a detachable connecting mechanism actuated by the turning of said knob or handle, substantially as described.

4. In a fire-lens lamp, in combination, a supporting-frame, a winding-cylinder mounted to turn therein, a crank or arm for turning said cylinder, a knob or handle arranged to turn in said crank or arm, and means supported by said crank or arm and controlled by the knob or handle arranged to connect said crank or arm to the cylinder upon a turning of said crank or arm in one direction and to disconnect said crank or arm from the cylinder upon a turning of the crank or arm in the reverse direction while holding the knob or handle, substantially as described.

arranged to connect said crank or arm to the cylinder upon a turning of said crank or arm in one direction and to disconnect said crank or arm from the cylinder upon a turning of the crank or arm in the reverse direction while holding the knob or handle, substantially as described.

5. In a fire-lens lamp, in combination, a supporting-frame, a winding-cylinder mounted to turn therein, a crank or arm for turning said cylinder, a sliding spring-pressed pawl carried by the crank or arm for connecting said crank or arm to the cylinder, and a knob or handle carried by said crank or arm and connected to said spring-pressed pawl for withdrawing the pawl and disconnecting the crank or arm from the cylinder, substantially as described.

6. In a fire-lens lamp, in combination, a supporting-frame, a winding-cylinder mounted to turn therein, a crank or arm for turning said cylinder, a detachable connecting mechanism between the crank or arm and cylinder, a pawl-and-ratchet device for actuating the detachable connecting mechanism, and a knob or handle for turning said crank or arm and actuating said pawl-and-ratchet mechanism when turned in a reverse direction to disconnect said crank or arm from the winding-cylinder, substantially as described.

7. In a fire-lens lamp, in combination, a supporting-frame, a winding-cylinder mounted to turn therein, a crank or arm for actuating said cylinder, a knob or handle mounted to turn in the free end of said crank or arm and a detachable connecting mechanism arranged to be operated to disconnect the crank or arm from the winding-cylinder by the turning of the knob or handle, substantially as described.

8. In a fire-lens lamp, in combination, a supporting-frame, a winding-cylinder mounted to turn therein, a crank or arm for turning said cylinder, a sliding spring-pressed pawl for connecting said crank or arm with the cylinder, a knob arranged to freely turn in said crank or arm, a ratchet secured to the inner end of said knob, and a spring-pawl connecting the sliding pawl with said ratchet, substantially as described.

9. In a fire-lens lamp, in combination, a supporting-frame, a winding-cylinder mounted to turn therein, a crank or arm detachably connected with said cylinder, a drag or brake for restraining the turning of said cylinder, said drag or brake arranged to be applied by lateral force applied to the crank or arm when disconnected from the winding-cylinder, substantially as described.

10. In a fire-lens lamp, in combination, a supporting-frame, a winding-cylinder and its shaft mounted to turn therein, a crank or arm detachably connected with the shaft for turning said cylinder, and fixed rollers carried by said shaft upon opposite sides of the crank or arm and arranged to frictionally engage said crank or arm when lateral force is applied thereto to restrain the turning of said winding-cylinder, substantially as described.

700,560. GRATE-FRONT AND FIREBOX. JOHN J. RELL, New York, N.Y. Filed Jan. 22, 1902. Serial No. 91,000. (No model.)

Claim.—1. In a device of the character described, the combination with end plates having a connecting-plate, of sections carrying means for limiting their movement in relation to each other, a top plate normally resting in the rear of said connecting-plate and adapted to engage the uppermost section, and means for movably mounting said sections within the end plates, substantially as described.

2. In a grate and fire-box, the combination of end plates and a connecting-plate, of an uppermost section carrying a flange and a lowermost section, and a second flange at its lower end, of a top plate movably secured at the upper end of the connecting-plate adapted for engagement with said uppermost section, said uppermost-section being movably mounted to the end plates, and means for adjusting the uppermost section, substantially as described.

3. The combination with the end plates having vertical slots therein and a connecting-plate having a horizontal slot therein, of a casing formed integral with said connecting-plate, a top plate carrying flanges secured in said casing, an uppermost section carrying T-heads engaging in said vertical slots, a flange formed integral with the lower end thereof, and a lowermost section carrying a flange for engagement with the flange of the uppermost section, and a flange on the lower end of said lowermost section, substantially as described.

4. The combination with a pair of end plates spaced apart and having vertical slots formed therein, and a horizontal plate having a horizontal slot therein secured to the said end plates at their upper portions, of a casing formed integral with the said horizontal plate upon its rear face, a top plate having depending flanges at its opposite sides seated within the said casing, sections formed with end flanges fitting in the said vertical slots, each of said sections carrying means for limiting their movement in relation to each other, and adapted to telescope one within the other when lowered, said top plate adapted to be drawn outwardly and fit over the upper edge of the upper section, substantially as described.

700,561. MEDICAL CABINET. WENDELL S. ROWLEY and LAWRENCE R. FERRIS, Indianapolis, Ind. Filed Aug. 6, 1901. Serial No. 78,851. (No model.)

Claim.—1. In a medical cabinet, the combination with the cabinet, of an air-compressor, a supply-pipe leading therefrom, an adjustable pressure-reducing valve mounted therein, a series of branch pipes leading from said supply-pipe, a valve arranged in each of said branch pipes, a reduction-pipe connected to each valve, and a series of medicine-receptacles arranged one between each reduction-pipe and adjacent discharge-nozzle.

2. In a medical cabinet, the combination with the cabinet, of an air-compressor, a supply-pipe leading therefrom, an adjustable pressure-reducing valve mounted therein, a series of branch pipes leading from said supply-pipe, a valve arranged in each of said branch pipes, a reduction-pipe connected to each valve, a series of discharge-nozzles discharging into the cabinet, and a series of medicine-receptacles removably mounted between each reduction-pipe and adjacent discharge-nozzle.

3. In a medical cabinet, the combination with a cabinet, of an air-compressor, a supply leading therefrom, a valve arranged in said supply-pipe, a reduction-pipe connected to said valve, a discharge-nozzle discharging into the cabinet, and a medicine-receptacle mounted between the reduction-pipe and discharge-nozzle.

4. In a medical cabinet, the combination with the cabinet, of an air-compressor, a supply-pipe leading therefrom, a series of branch pipes leading from said supply-pipe, a valve arranged in each of said branch pipes, a reduction-pipe connected to each valve, a series of discharge-nozzles discharging into the cabinet, and the series of medicine-receptacles removably mounted between each reduction-pipe and adjacent discharge-nozzle.

700,562. KNIFE-SHARPENING DEVICE. ARTHUR F. RELL, New York, N.Y. Filed Jan. 2, 1902. Serial No. 92,545. (No model.)

Claim.—1. A knife-sharpening device comprising a plate or support, parallel tracks or ways connected with one side of said support, a slide movable longitudinally of said tracks or ways and provided in the top thereof with a longitudinal opening which is V-shaped in cross-section, substantially as described.

tion, stones or disks placed in the opposite sides of said opening and at the opposite ends thereof, a crank-wheel connected with said plate or support and in operative connection with said disks, said plate or support being also provided with upwardly-directed members having downwardly-directed arms provided with vertically-adjustable jaws adapted to hold a knife-blade so that the edge thereof will pass between said stones or disks, substantially as shown and described.

2. A knife-sharpening device comprising a plate or support, parallel and longitudinal tracks or ways connected therewith, a slide movable longitudinally of said tracks or ways and provided at the top thereof with an opening, stones or disks placed in the opposite sides of said opening and at the opposite ends thereof and operated by an inclined screw, means for reciprocating said slide longitudinally of the plate or support and vertically-adjustable devices for mechanically holding a knife over said slide so that the blade will enter the space between the stones or disks, substantially as shown and described.

700,568. PROCESS OF EXTRACTING METALS FROM ORES AND SCRAP CONTAINING SAME. SAMUEL S. SARTER, Philadelphia, Pa. Filed July 10, 1902. Renewed Apr. 11, 1903. Serial No. 100,497. (No specimen.)

Claim.—1. The process of obtaining the metals, whose oxides form soluble compounds with the alkali-metal hydroxide, from any material in which these metals are present, said process consisting in treating said material with a solution formed by treating a caustic alkali with one of the halogens and decomposing the resulting solution in an electrolytic cell, the metal being deposited on a suitable cathode, substantially as described.

2. The process of obtaining from their solid ore metals whose oxides form soluble compounds with the alkali-metal hydroxide, said process consisting in dissolving the ore in a solution formed by treating a solution of a caustic alkali with any one of the halogens, and decomposing the resulting solution in an electrolytic cell, substantially as described.

3. The process of extracting from their solid ore metals whose oxides form soluble compounds with the alkali-metal hydroxide, said process consisting in dissolving said ore in a solution formed by treating a solution of a caustic alkali with a halogen and decomposing the resulting solution in the cathode-compartment of an electrolytic cell, the anode-compartment being separated therefrom, and containing a solution of caustic alkali, substantially as described.

4. The process of extracting from their ore metals whose oxides are soluble in the alkali-metal hydroxide, said process consisting in dissolving said ore in a solution formed by treating a solution of caustic alkali with a halogen, decomposing the resulting solution in the cathode-compartment

ment of an electrolytic cell, and in the anode-compartment of said cell simultaneously regenerating a solution from which metal has previously been separated, said solution having been transferred from the cathode to the anode compartment before beginning the operation, substantially as described.

5. The herein-described process of extracting from their solid ore metals whose oxides form soluble compounds with the alkali-metal hydroxide, said process consisting in dissolving said ore in a solution of sodium hypochlorite and sodium hydroxide, separating the sulfur therein formed, and decomposing the remaining solution in the cathode-compartment of an electrolytic cell, substantially as described.

6. The process of extracting zinc from the solid ore of the same, said process consisting in dissolving said ore in a solution containing sodium hypochlorite and sodium hydroxide, separating the sulfur therein formed, decomposing the remaining solution in the cathode-compartment of an electrolytic cell, and simultaneously regenerating, in the anode-compartment of said cell, a solution of sodium hydroxide left in the cathode-compartment and transferred therefrom to the anode-compartment after a previous operation of the same cell, substantially as described.

700,564. TRUCK-MOUNTED. RALPH V. BARK, Johnstown, Pa. Filed Oct. 18, 1901. Serial No. 79,514. (No model.)

Claim.—An improved holder of the class described, comprising two I-beams parallel to each other, having their outside flanges at the ends cut away; plates secured on the outside of said ends to serve as guides for the truck-columns; adjustable couplings secured between the ends of the beams and adapted to receive the holder-springs; and a pair of channels secured between said beams intermediate the ends of said holder and adapted to receive the king-pins between them.

700,565. ADDITIVE AND PROCESS OF MAKING SAME. OTHMAR BURBAUGH and HANS F. BOESCHMANN, Ludwigshafen, Germany, assignors to the Badische Anilin & Soda-Fabrik, Ludwigshafen, Germany, a Corporation of Baden. Filed Jan. 15, 1901. Serial No. 48,771. (Specimen.)

Claim.—1. The process for the production of new azo coloring-matters by combining together 1,8-naphthalene-diamine-sulfate-acid, acetone and a dye body.

2. The process for the production of new azo coloring-matters by combining together 1,8,8'-naphthalene-diamine-sulfate-acid, acetone and a dye body.

3. The new azo coloring-matter which can be derived from 1,8-naphthalene-diamine-sulfate-acid, acetone and a dye body, and which in the form of their sodium salts are soluble in water with a violet-red to blue color, and in concentrated sulfuric acid with a blue to green color; which dye wool violet-red to blue, and whose aqueous solution by the addition of hydrochloric acid produces a dark-violet to green precipitate, and which when boiled with dilute carbonate-of-soda solution, containing about one per cent. of Na_2CO_3 , or with dilute sulfuric acid, containing about five per cent. of H_2SO_4 , for ten minutes are not decomposed, substantially as hereinafter described.

4. The new azo coloring-matter which can be derived from 1,8,8'-naphthalene-diamine-sulfate-acid, acetone, and disodium-pyrazine-sulfate which in the form of its sodium salt is soluble in water with a blue color, and in concentrated sulfuric acid with a green color; which dye wool blue, and whose aqueous solution by the addition of hydrochloric acid produces a blue precipitate, and which when boiled with dilute carbonate-of-soda solution, containing about one per cent. of Na_2CO_3 , or with dilute sulfuric acid, containing about five per cent. of H_2SO_4 , for ten minutes is not decomposed, substantially as hereinafter described.

700,566. POTATO-PLANTER. FREDERICK SCHWAB, Leipzig, Klass-Schlesier, Germany, assignor to Max Steinberg, Leipzig, Germany. Filed July 9, 1901. Serial No. 67,578. (No model.)

Claim.—1. In a potato-planter a container provided with a partition dividing the same into a storage-compartment and a forward or spreading compartment in which the potatoes can spread into a thin layer of uniform thickness irrespective of the greater or less supply of potatoes in the storage-compartment, the lower edge of the partition being above the bottom of the container to thereby provide an opening, a curved portion

tion in said forward compartment, a wheel having arms provided with potato-carrying devices, and means adjacent to said curved portion for forcing superfluous potatoes from said potato-carrying devices and onto said curved portion.

2. In a potato-planter a container provided with a partition dividing the same into a storage-compartment and a forward or spreading compartment in which the potatoes can spread into a thin layer of uniform thickness irrespective of the greater or less supply of potatoes in the storage-compartment, the lower edge of the partition being above the bottom of the container to thereby provide an opening, a curved portion in said forward compartment, a wheel having arms provided with potato-carrying devices, means adjacent to said curved portion for forcing superfluous potatoes from said potato-carrying devices and onto said curved portion, a tube located to receive potatoes from said potato-carrying devices, and a valve made to swing or open and close in said tube in the direction transversely to the travel of the planter.

3. In a potato-planter, a container, a wheel having arms provided with potato-carrying devices, a tube having a valve, a lever disposed in the path of the arms and adapted to be operated thereby, and a connection between said lever and valve, said valve being made to open in the direction transversely to the travel of the planter so as to prevent the outgoing potato from rolling along the furrow.

4. In a potato-planter, a container, a wheel having arms provided with potato-carrying devices and a tube to receive the potatoes, a wall of the tube having a slot consisting of wide portions and an intermediate narrow portion one of said wide portions having fingers in the same.

5. In a potato-planter, a container having a plurality of communicating compartments, a potato-spreading space or portion in the forward compartment, a wheel having arms arranged to travel through the forward compartment, said arms having potato-carrying devices, a tube arranged to receive the potatoes from said potato-carrying devices and adapted for the passage of said arms, and means in the forward compartment to expel superfluous potatoes from said potato-carrying devices.

6. In a potato-planter, a container having a plurality of communicating compartments, a curved portion in the forward compartment, a wheel having arms arranged to travel through the forward compartment, said arms having potato-carrying devices, a tube arranged to receive the potatoes from said potato-carrying devices and adapted for the passage of said arms, means in the forward compartment to expel superfluous potatoes from said potato-carrying devices, and means for regulating the movement of the potatoes from the rear to the forward compartment.

7. In a potato-planter, a container for potatoes, provided with a partition for dividing the same into compartments the lower edge of the partition being above the bottom of the container to thereby provide an opening, a wheel located below the container and provided with arms, a tube at the forward end of the container and arranged transversely therein and the lower wall of the tube and the bottom of the container being adapted for the passage of said arms, potato-carrying devices on the arms, and means in said tube for positively discharging the potatoes from said potato-carrying devices as they enter the tube.

8. In a potato-planter, a container for potatoes, a tube, means for carrying the potatoes from the container to the tube, means in said tube for positively discharging the potatoes from the carrying means, a valve for said tube, formed of a wedge-shaped plate and made to open transversely of the direction of travel of the planter, a plowshare for the tube, and means for automatically opening said valve.

700,567. KIM. FRANK A. HERRICK, Buffalo, N. Y. Filed Feb. 24, 1902. Serial No. 82,100. (No model.)

Claim.—1. A bag having its staves provided with curved side edges and an integral tongue projecting from one of said side edges of each stave of equal size and thickness throughout which terminates near each end of the stave in abrupt shoulders, and a longitudinal groove in the other side edge of equal depth throughout corresponding in size and form to the

tongue and terminating in an abrupt shoulder at each end, substantially as set forth.

2. In a bag, head, a series of staves having transverse grooves in their inner faces forming chimneys for said heads and side tongue-and-groove connections which terminate at points beyond the transverse grooves and within the ends of the staves in abrupt opposed shoulders, substantially as described.

3. A bag having head, and a plurality of staves with chimneys in which the heads rest and interlocking tongues and grooves which extend beyond the chimneys and terminate within the ends of the staves.

700,568. CHIMNEY COWL OR VENTILATOR. HERMAN SURVANCE, New York, N. Y. Filed Dec. 13, 1901. Serial No. 64,061. (No model.)

Claim.—1. In a chimney-cowl, the combination, with a main trunk having openings in its side walls and side extension-wings, of a vertically-adjustable hood guided over said main trunk and side extension-wings, valves for closing said openings, and means for operating simultaneously said valves with the adjustment of said hood, substantially as set forth.

2. In a chimney-cowl, the combination, with a main trunk having openings in its side walls and side extension-wings, of a vertically-adjustable hood guided over said main trunk and side extension-wings, valves hinged at their bottom edges to the side walls of said main trunk, a spring-expanded means guided in said main trunk and supporting said hood, and means connected therewith for opening said valves simultaneously with the adjusting of said hood, substantially as set forth.

3. The combination, with a main trunk provided with openings in its side walls, of side extension-wings at the corners of the trunk, valves hinged to the side walls of said trunk and adapted to close the side openings in the trunk, a hood supported above the trunk, a spring-expanded guide-frame in said trunk connected with said hood, pivot-straps connecting the guide-frame with the valves, and a chain connected with the guide-frame for lowering the guide-frame and hood and closing the valves, substantially as set forth.

700,569. VALVE REVERSE FOR STEAM-HEATING SYSTEMS. JOHN A. BARNARD, Bayonne, N. J., assignor to WATSON WHEELER and Company, a Corporation of New Jersey. Filed Mar. 19, 1900. Serial No. 5,126. (No model.)

Claim.—In a valve device for a steam-heating system in which a cushion or lower pressure is produced in the return from the outlet of each valve device, the combination of a valve-body having an inlet and an outlet and a thoroughfare for the passage of water of condensation, an automatically-controlled valve-plate to control said thoroughfare, and an auxiliary check-valve also controlling said thoroughfare and arranged so as to be kept normally open by the cushion or lower pressure in the outlet of the valve-body.

700,570. INSULATOR-SUPPORTING ARM. JOHN R. SHARP, Ocala, N. Y., assignor of one-half to Norton D. Bartin, Ocala, N. Y. Filed Dec. 28, 1901. Serial No. 87,315. (No model.)

Claim.—1. An insulator-supporting arm consisting of a prolonged metallic plate formed transversely with a horizontal central portion and with stiffening-flanges depending from the edges of said central portion, in combination with an insulator mounted on the horizontal central portion of the arm, bars disposed across the bottom of the arm and bearing on the bottom edges of the flanges, and bolts tying the insulator to said bars.

2. An insulator-supporting arm consisting of a prolonged metallic plate formed transversely with a horizontal central portion and with longitudinal flanges depending from the edges of the central portion, bars disposed across the bottom of the flanges and provided with shoulders engaging the sides of the flanges, and bolts tying the insulator to said bars as set forth.

3. An insulator-supporting arm consisting of a prolonged metallic plate formed transversely with a rest in its center and with longitudinal flanges depending convergently from the edges of the rest, in combination with the insulator mounted on said rest, bars disposed across the bottom of the flanges, and bolts tying the insulator to said bars.

4. As an improved article of manufacture, an insulator-supporting arm formed of a prolonged metallic plate bent transversely into the shape of flanges depending from a straight central portion, the flanges of the attaching portion of the arm being parallel and the flanges of the free end portions being converging downward as set forth and shown.

700,571. DUMPING-VEHICLE. HENRY F. SHENK, Brooklyn, N. Y. Filed Feb. 12, 1902. Serial No. 93,002. (No model.)

Claim.—1. In a dumping-vehicle, a bed-frame, a body mounted to slide on the bed, a tail-board for the body, supporting-bars for the tail-board and carried by the body, and rollers on the bed with which the bars engage, substantially as specified.

2. In a dumping-vehicle, a rearwardly and downwardly inclined bed, a body, rollers carried by said body and engaging on said bed, supporting-bars attached to the bed and engaging over said rollers, a locking-latch mounted to swing on the forward end of the bed, a device carried by the body for engaging with said latch, and an opening-lever having connection with said latch, substantially as specified.

3. In a dumping-vehicle, a bed-frame comprising side rails inclined downward and rearward, a body, rollers carried by said body and engaging on said side rails, a tail-board, angular supporting-bars for said tail-board, the said bars being mounted to swing on the journals of the said rollers, and rollers mounted on said side rails and engaging with the forward portions of said bars, substantially as specified.

4. In a dumping-vehicle, a downwardly and rearwardly inclined bed, a body, rollers carried by said body and engaging on said bed, the said rollers having flanges on their outer sides to engage against the outer sides of the bed, a tail-board extending of two hinged sections, angular supporting-bars for said tail-board, the said bars being mounted on the journals of the rollers, rollers on the bed for engaging with the forward portions of said bars, and locking devices for the tail-board, substantially as specified.

5. In a dumping-vehicle, a bed inclined downward and rearward, a body, rollers carried by said body and engaging on the bed, a tail-board, angular supporting-bars for said tail-board, the said bars being mounted on the journals of the rollers, rollers mounted on the bed for engaging the forward portions of the bars, plates on the ends of the tail-board, and weighted hooks mounted on the body for engaging with said plates, substantially as specified.

6. In a dumping-vehicle, a bed inclined downward and rearward, a body mounted to slide on said bed, a locking-latch at the forward end of the bed, a roller carried by the body for engaging with said locking-latch, and a rearward-bar attached to the front portion of the bed and engaging with the upper side of said roller, substantially as specified.

7. In a dumping-vehicle, a bed, a body mounted to slide on said bed and to tilt on the same, springs supporting the rear portion of the bed, the said springs being extended rearward to form buffers for the body when moved to its dumping position, and link connections between the rear ends of the springs and the bed, substantially as specified.

8. In a dumping-vehicle, a downward and rearwardly inclined bed-frame comprising side rails, a body, rollers carried by said body for engaging on the said side rails, the forward portions of the side rails being extended upward to a point substantially on a line with the tops of the rollers, a tail-board, means for locking the tail-board to the body, and means movable with the body for disengaging the tail-board from the locking means, substantially as specified.

700,572. VENTILATOR. HARRY M. SMITH, West River Fall, Wt. Filed Jan. 31, 1901. Serial No. 45,478. (No model.)

Claim.—1. In a ventilator, the combination with a casing consisting of a bottom piece, end pieces, and a back piece, said back piece having its upper edge bent over slightly, of a horizontal partition arranged above the bottom piece, and extending from end to end of the casing, and having its inner edge terminating short of the back piece, and beneath the bent-over upper edge of said back piece, a lower opening being formed between the under side of the horizontal partition and the upper side of the bottom piece for the entrance of the external air into the casing, and an upper opening being formed between the upper side of the partition and the bent-over upper edge of the back piece, the latter opening adapted for the escape of the air from the casing into the structure to be ventilated.

2. In a ventilator, the combination with a casing consisting of a bottom piece, end pieces, and a back piece, said back piece having its upper edge bent over slightly, of a horizontal partition arranged above the bottom piece and extending from end to end of the casing, and having its inner

edge terminating short of the back piece, and beneath the bent-over upper edge of said back piece, a lower opening being formed between the under side of the horizontal partition and the upper side of the bottom piece for the entrance of the external air into the casing, and an upper opening being formed between the upper side of the partition and the bent-over upper edge of the back piece, the latter opening adapted for the escape of the air from the casing into the structure to be ventilated, and a device carried at the outer edge of the horizontal partition, and adapted for supporting the lower edge of a window.

3. In a ventilator, the combination with a casing consisting of a bottom piece, end pieces, and a back piece, said back piece having its upper edge bent over slightly, of a horizontal partition arranged above the bottom piece and extending from end to end of the casing, and having its inner edge terminating short of the back piece and beneath the bent-over upper edge of said back piece, a lower opening being formed between the under side of the horizontal partition and the upper side of the bottom piece for the entrance of the external air into the casing, and an upper opening being formed between the upper side of the partition and the bent-over upper edge of the back piece, the latter opening adapted for the escape of the air from the casing into the structure to be ventilated, a rock-shaft at the inner edge of the horizontal partition, said shaft having one end extended outwardly and provided with a hand-crank, a gate-valve within the casing and mounted on the rock-shaft, and means carried by the end of the casing for making the hand-crank rotate in adjusted position.

4. In a ventilator, a casing consisting of a bottom piece, end pieces, a back connected to the bottom piece and having its upper edge extending forward of the back of said bottom piece, and a partition extending longitudinally of said casing and from the front thereof toward the back; all arranged so that air may enter said casing between the bottom and the partition and leave between the partition and the upper edge of the back; and a gate within said casing whereby the passage of air through said casing may be wholly or partially checked as desired.

5. In a ventilator, a casing consisting of a bottom, ends and a back having its upper edge extending slightly toward the front of said casing, a partition arranged above the bottom and extending longitudinally thereof with its inner edge terminating short of the back and beneath the upper edge of the back; said parts arranged to form an opening for air admission between the partition and the bottom and an opening for air escape between the partition and the upper edge of the back; movable means in said casing for wholly or partially checking the passage of air through the ventilator, and mechanism for holding said means in different positions.

6. In a ventilator, a casing consisting of a bottom, ends and a back having its upper edge extending slightly toward the front of said casing, a partition arranged above the bottom and extending longitudinally thereof with its inner edge terminating short of the back and beneath the upper edge of the back; said parts arranged to form an opening for air admission between the partition and the bottom and an opening for air escape between the partition and the upper edge of the back; movable means in said casing for wholly or partially checking the passage of air through the ventilator, and mechanism for holding said means in different positions.

7. In a ventilator, a casing consisting of a bottom, ends and a back having its upper edge extending slightly toward the front of said casing, a partition arranged above the bottom and extending longitudinally thereof with its inner edge terminating short of the back and beneath the upper edge of the back; said parts arranged to form an opening for air admission between the partition and the bottom and an opening for air escape between the partition and the upper edge of the back; and movable means in said casing for wholly or partially checking the passage of air through the ventilator.

700,573. FUELER. WARREN R. SMITH, Marlboro, Mass. Filed Aug. 28, 1901. Serial No. 72,064. (No model.)

Claim.—In a fueler, a box containing two blocks, one for each burner, adapted to coast one hundred in to a addition; blocks 1, 2, 3, 4, 5,

6, 7 being so disposed in two columns that when added their total will be equal to the blocks 8, 9, 10 in the order stated, and the blocks 9, 10 in the order stated, disposed beneath the blocks 8, 9, whereby the sum total of 190 is obtained.

700,574. INCANDESCENT GAS-BURNER. CLARENCE W. TAYLOR, West City, Iowa. Filed Mar. 18, 1902. Serial No. 93,002. (No model.)

Claim.—1. In an incandescent gas-burner, the combination with a mantle and a burner-tube provided with air-inlets, of a mixing-tube having a portion thereof surrounding said burner-tube and provided with an enlarged portion arranged above the burner-tube forming a gas and air mixing chamber, said lower portion of the mixing-tube forming air-passages between the same and the burner-tube and further provided with air-inlets, and a cap mounted upon the enlarged portion of the mixing-tube and adapted to form independent air-passages between the said enlarged portion and the inner face of the side walls of the cap.

2. In an incandescent gas-burner, the combination with a mantle and a burner-tube provided with air-inlets, of a mixing-tube having a portion thereof surrounding said burner-tube and provided with an enlarged portion arranged above the burner-tube forming a gas and air mixing chamber, said lower portion of the mixing-tube forming air-passages between the same and the burner-tube and further provided with air-inlets, a cap mounted upon the enlarged portion of the mixing-tube and adapted to form independent air-passages between the said enlarged portion and the inner face of the side walls of the cap, and means arranged in the burner-tube and operated by the mixing-tube for regulating the supply of gas.

3. In an incandescent gas-burner, a mixing-tube constructed of an upper and lower portion of different diameters, the smaller of which is provided with a vertical groove at the bottom and the larger of which forms a gas and air mixing chamber, and a cap mounted upon the said larger portion of said mixing-tube and adapted to form an air-passages between the same and said larger portion.

4. In an incandescent gas-burner, the combination with a burner-tube connected to a gas-supply and provided with air-inlets, of a mantle arranged in the said tube for regulating the supply of gas through a mixing-tube surrounding the said burner-tube and having its upper portion forming a mixing-chamber and its lower portion adapted to engage said regulating means for operating it, and a cap mounted upon the upper portion of the mixing-tube and adapted to form an air-passages between the mixing-tube and the wall thereof.

5. In an incandescent gas-burner, the combination of a nipple connected to a gas-supply and provided with a peripheral flange and a shoulder, a burner-tube mounted upon said shoulder and provided with air-inlets, a rotatable mixing-tube mounted upon said flange, surrounding said burner, provided with air-inlets and forming air-passages between the burner and inner face of said mixing-tube, said mixing-tube forming in its upper portion the gas and air mixing chamber, a cap mounted upon the upper portion of the mixing-tube to form an air-passages, and means arranged in the burner-tube and operated by the mixing-tube for regulating the supply of gas to the burner.

6. In an incandescent gas-burner, a burner-tube, a rotatable mixing-tube surrounding said burner-tube and forming air-passages between the same and the inner face of said mixing-tube, and a plate arranged in the burner-tube and operated by the mixing-tube for regulating the supply of gas.

7. In an incandescent gas-burner, the combination with a burner-

tube connected to a gas-supply, of a rotatable mixing-tube surrounding the same and having its upper portion terminating in a gas and air mixing chamber and its lower portion formed with an offset, a plate arranged in the burner-tube and adapted to regulate the supply of gas and a stud integral with the plate and engaging in the offset of the mixing-tube so as to cause the operation of the plate when the said mixing-tube is rotated.

8. In an incandescent gas-burner, the combination with a burner-tube provided with beads, of a rotatable mixing-tube surrounding the burner-tube and engaging the beads for retaining it in a uniform position, air-passages formed between the burner-tube and the mixing-tube, air-inlets provided in the mixing-tube, a plate arranged in the burner-tube for regulating the supply of gas, and means carried by the plate and engaged by the mixing-tube for causing the operation of the plate when the mixing-tube is rotated.

9. In an incandescent gas-burner, a nipple connected to a gas-supply and provided with an annular shoulder and a peripheral flange, a perforated diaphragm connected to the top of the nipple, a burner-tube connected to the nipple and engaging the shoulder thereof, said burner-tube provided with a slot, air-inlets above the said slot and a plurality of beads, a rotatable mixing-tube surrounding the burner-tube and mounted upon the flange of the nipple, said mixing-tube provided with air-inlets and an offset, a plate mounted upon the diaphragm and adapted to regulate the supply of gas therethrough, and a stud integral with the plate extending through the slot of the burner-tube into the offset of the mixing-tube and adapted to cause the operation of said plate when the mixing-tube is rotated.

700,575. SOLDERLESS SIDE SEAM FOR THE CASE. WALTER THOMPSON, Toronto, Canada, assignor, by mesne assignments, to the Pathefr's Sanitary Can Company, Paterson, N. J., a Corporation of New Jersey. Filed Feb. 2, 1902. Serial No. 92,302. (No model.)

Claim.—1. A solderless side seam formed with a series of transversely-extending depressions extending substantially from end to end of the seam, and also formed with a longitudinal portion thereof extending also substantially from end to end of the seam depressed out of the plane of the parallel immediately-contiguous portion of said seam, substantially as described.

2. A solderless side seam having a longitudinal depression extending substantially from end to end thereof, the bottom of said depression being transversely indented, substantially as described.

3. A solderless side seam having a longitudinal depression extending substantially from end to end of said seam and also having a series of transverse depressions crossing said longitudinal depression, substantially as described.

700,576. SOLDERLESS END SEAM FOR THE CASE. WALTER THOMPSON, Toronto, Canada, assignor, by mesne assignments, to the Pathefr's Sanitary Can Company, Paterson, N. J., a Corporation of New Jersey. Filed Feb. 2, 1902. Serial No. 92,303. (No model.)

Claim.—1. A sheet-metal vessel having a head inclosed within the vessel-body and provided with a flange snugly fitting the same, the edge portions of said body and flange being bent back so as to form themselves and a portion of said vessel below the head and comprising coincident portions of the head and body having the form of a hand-like conical frustum, substantially as described.

2. The combination of a body member and a head member inclosed within said body member and having a flange snugly fitting within the same, coincident portions of the body and the flange of said head being

formed as a hand-like conical frustum, and means for maintaining pressure on the head-member in the direction of that portion of the body member which has the conical frustum form, substantially as described.

3. The combination of a body member and a head member inclosed within said body member and having a flange snugly fitting within the same, one of said members having its edge portion bent around the edge portion of the other and tending to force the head member longitudinally of the vessel, a part of the vessel which comprises coincident portions of the body and head being formed as a hand-like conical frustum so disposed that the body portion offers resistance against movement of the head portion, substantially as described.

700,577. SOLDERLESS SIDE SEAM FOR THE CASE. WALTER THOMPSON, Toronto, Canada, assignor, by mesne assignments, to the Pathefr's Sanitary Can Company, Paterson, N. J., a Corporation of New Jersey. Filed Feb. 2, 1902. Serial No. 92,302. (No model.)

Claim.—1. A sheet-metal vessel provided with a side seam and having contiguous and parallel longitudinal beads formed the one in one longitudinal edge portion of the seam of said vessel and the other in the adjacent portion of the body of the vessel, substantially as described.

2. A sheet-metal vessel provided with a side seam and having the longitudinal edge portion of said side seam and the portion of the metal of the body of the vessel immediately adjacent to and parallel with said edge portion bent inwardly to form a longitudinal depression in said vessel, substantially as described.

3. A sheet-metal vessel provided with a side seam and having the edge portions of said side seam depressed out of the plane of the adjacent portion of the material forming the body of the vessel, substantially as described.

4. A sheet-metal vessel provided with a side seam and having the portion of the metal thereof which comprises the contiguous portions of the seam and body of the vessel pressed inwardly from end to end of said vessel, substantially as described.

700,578. END SEAM FOR THE CASE. WALTER THOMPSON, Toronto, Canada, assignor, by mesne assignments, to the Pathefr's Sanitary Can Company, Paterson, N. J., a Corporation of New Jersey. Filed Mar. 18, 1902. Serial No. 97,472. (No model.)

Claim.—1. A sheet-metal vessel having the edge portions of its head and body bent back upon themselves to produce an annular roll-like flange, said flange being provided with substantially transverse spaced indentations, substantially as described.

2. A sheet-metal vessel having an annular flange and head forming the end portion thereof, said flange and head being provided with substantially transverse indentations, substantially as described.

700,579. CULTIVATOR. MARCUS J. YOUNG, Buffalo, N. Y. Filed Nov. 11, 1901. Serial No. 31,912. (No model.)

Claim.—1. In a straddle-row cultivator, in combination, two gangs, the inner shovel of each gang being capable of being shifted laterally, means connected to each inner shovel for normally holding them in working line relative to the other shovels of their respective gangs, and means for acting on each former means for shifting laterally the inner shovels, as set forth.

2. In a straddle-row cultivator, in combination, two gangs, the inner shovel of each gang being capable of being shifted laterally, means connected to each inner shovel for normally holding them in working line relative to the other shovels of their respective gangs, means for acting on each former means for shifting laterally the inner shovels, and means connecting each inner shovel to their respective gangs whereby all of the shovels of a gang may move vertically in unison, as set forth.

3. In a straddle-row cultivator, in combination, two gangs, the inner shovels of each gang being shiftable laterally independently of the other shovels thereof, mechanism connected to each inner shovel for shifting the same laterally, means for causing the shifting mechanisms to move in unison, the shifting mechanisms of the two gangs being so arranged relatively that when the inner shovel of either gang is moved laterally the position of the inner shovel of the other gang remains practically unchanged, as set forth.

4. In a straddle-row cultivator, in combination, two gangs, the inner shovel of each gang being shiftable laterally independently of the other shovels thereof, mechanism carried by each gang connected to the inner shovel thereof for shifting the same laterally, a connection between each mechanism of the two inner shovels, and actuating means, each shifting mechanism of the two gangs being so arranged relatively that when the inner shovel of either gang is moved laterally the position of the inner shovel of the other gang remains practically unchanged, as set forth.

5. The combination with the gangs, the inner shovel of each gang being shiftable laterally independently of the other shovels thereof, of shifting devices connected to each of the inner shovels, foot-levers connected to each device, and a connection between the two devices, each device of the two gangs being so arranged relatively that in the movements thereof but one shovel at a time will be shifted laterally, substantially as set forth.

6. The combination with the gangs, the inner shovel of each gang having a separate drag-bar capable of moving laterally, of shifting devices pivoted to each drag-bar and carried by the gangs, levers connected to each device, and a connection between the two levers, substantially as set forth.

7. The combination with the gangs, the inner shovel of each gang having a separate drag-bar capable of moving laterally, of shifting devices pivoted to each drag-bar, a guide for each device on each gang, two foot-levers connected each to one of the shifting devices, and a connection between the two foot-levers, substantially as set forth.

8. The combination with the gangs, the inner shovel of each gang having a separate drag-bar capable of moving laterally, of shifting devices for the inner shovel of each gang, each device being pivotally connected to each shovel, guides on the gangs for each device, the latter when moving in each guide effecting the shifting of their respective shovels only throughout a portion of each movement, a connection between the two shifting devices, and means for actuating the latter, said shifting devices being so arranged relatively that as the inner shovel of one gang is shifted laterally to narrow the cut of each gang the inner shovel of the other gang remains practically unmoved, as set forth.

9. In a straddle-row cultivator, in combination, two gangs, the in-

ner shovel of each gang being shiftable laterally independently of the other shovels thereof, carrying-wheel, axle therefor having pivot-spindles, and means for shifting the wheel and the inner shovel simultaneously, as set forth.

10. In a straddle-row cultivator, in combination, two gangs, the inner shovel of each gang being shiftable laterally independently of the other shovels thereof, carrying-wheel, axle therefor having pivot-spindles, means connecting the inner shovel of each gang to one of the axles, and means for shifting the wheel and the inner shovels simultaneously, as set forth.

11. In a straddle-row cultivator, in combination, two gangs, the inner shovel of each gang being shiftable laterally independently of the other shovels thereof, carrying-wheel, axle therefor having pivot-spindles, means connected to each inner shovel for shifting the same laterally, connections between each means and the axle, said shifting means being so arranged relatively that as the inner shovel of one gang is shifted laterally to narrow the cut of each gang the inner shovel of the other gang remains practically unmoved, and means for simultaneously shifting the wheel and the shifting means of the two inner shovels, substantially as set forth.

12. In a straddle-row cultivator, in combination, two gangs, the inner shovel of each gang being so mounted that it may be shifted laterally independently of the other shovels thereof, carrying-wheel, pivoted axle therefor, and means for simultaneously shifting laterally the carrying-wheel and the inner shovels, as set forth.

13. In a straddle-row cultivator, in combination, two gangs, the inner shovel of each gang being so mounted that it may be shifted laterally independently of the other shovels thereof, carrying-wheel, pivoted axle therefor, means for shifting laterally the inner shovels, and means connected to the last-mentioned means and to the axle for shifting the wheel and the shifting means of the inner shovels simultaneously, as set forth.

14. In a straddle-row cultivator, in combination, two gangs, the inner shovel of each gang being capable of being shifted laterally independently of the other shovels, means connecting each inner shovel to their respective gangs whereby all the shovels of a gang may move vertically in unison, carrying-wheel, axle therefor having pivot-spindles, means for shifting laterally the inner shovels, and means connected to the last-mentioned means and to the axle for shifting the wheel and the shifting means of the inner shovels simultaneously.

15. The combination with the gangs, the inner shovels of which are independently shiftable, of means movable on each gang for so shifting the inner shovels, foot-levers connected to each means, carrying-wheel, axle having pivot-spindles to which each foot-lever is connected, and a connection between each foot-lever, substantially as set forth.

16. The combination with the gangs, of levers for raising and lowering the same, a seat for the operator, and a support therefor itself supported by said levers and so connected thereto as to equalize the weight of and aid in lifting the gangs, as set forth.

17. The combination with the gangs, of levers for raising and lowering the same, a seat for the operator, a support for each seat, and means interconnecting the seat-support and the levers whereby each support is itself supported by the levers so that the weight of the operator is utilized to offset the weight of and aid in lifting the gangs, as set forth.

18. The combination with the gangs, of levers for raising and lowering the same, a seat for the operator, a lever on which each seat is mounted, and a support for each seat-lever connected to and supported by said levers at points adjacent the fulcrum thereof as to utilize the weight of the operator to offset that of the gangs and aid in lifting the latter, as set forth.

19. The combination with the gangs, of the levers for raising and lowering the same, a seat for the operator, a lever on which each seat is mounted, a cross-rod forming a support for each lever, links supporting said cross-rod at its ends, said links being pivoted each to one arm of the lever adjacent thereto, the other arm of each lever being connected to its respective gang, substantially as set forth.

20. The combination with the cultivator-frame, and the gangs, of the levers, connections between each lever and the gangs, of a seat-lever fulcrumed on said frame, a cross-rod supported by said levers and in turn supporting said seat-lever, the connections of the cross-rod to said levers being adjacent to the fulcrum thereof, whereby the weight of the operator is communicated to the levers for equalizing the weight of the gangs, as set forth.

21. In a straddle-row cultivator, the combination with the frame having spaced-apart tongue-bars, of a yoke secured to, and depending from, said tongue-bars and capable of being vertically adjusted, means for binding and holding each yoke to each bar, and the gangs loosely secured at their forward ends to each yoke, as set forth.

22. In a straddle-row cultivator, the combination with the frame, of the yoke, means for adjustably securing the yoke to the frame, drag-gangs having drag-bars loosely hinged on lower portions of said yoke, and the

controlling-levers on the frame connected to the gangs, substantially as set forth.

23. The combination with the tongue having spaced-apart bars, of the yoke mounted between and adjustably secured to said bars, said yoke having lower outwardly-extended portions, the gangs loosely secured to said outwardly-extended portions, the controlling-levers, and connections between said levers and the gangs, substantially as set forth.

24. The combination with the spaced-apart bars, of the yoke between said bars having notches in its vertical portions, said bars having hooked ends provided with teeth for engaging such notches, said yokes having lower outwardly-extended portions, the gangs loosely secured to said outwardly-extended portions, the hand-levers, and connections between the latter and the gangs, substantially as set forth.

25. In a straddle-row cultivator, the combination with the frame, of the gangs pivoted at their forward ends, and means connecting the gangs to the frame at points intermediate the length of the gangs, such means being constructed to prevent lateral movement of the gangs, as set forth.

26. In a straddle-row cultivator, the combination with the yoke having outwardly-extended portions, of the gangs loosely secured to such portions, and means connecting the gangs to the frame at points intermediate the length of the gangs, such means being constructed to prevent lateral movement of the gangs, as set forth.

27. In a straddle-row cultivator, the combination with the frame, the wheels and the pivot-axles, of the gangs pivoted at their forward ends, and a non-flexible link secured to each gang at a point intermediate its length and also secured to the frame, the connection between the links and the gangs permitting the latter to move vertically, but not laterally substantially as set forth.

28. In a straddle-row cultivator, the combination with the frame having depending slotted portions, the wheels and the axles, of the gangs pivoted at their forward ends, and non-flexible links connecting each slotted portion with the gangs at points intermediate the lengths of the latter for preventing lateral movement thereof and allow them to move vertically, as set forth.

29. In a straddle-row cultivator, the combination with the frame and the yokes, of the gangs secured at their forward ends to the yokes, the carrying-wheels, axles therefor having pivot-spindles, hangers for such spindles adjustably mounted on the frame, dotted plates carried by the frame in line with the axles, links connecting the gangs to such dotted plates, the lower ends of each gang being shiftable laterally independently of the other shafts thereof, and means for shifting each inner shaft, substantially as set forth.

700,580. VEHICLE. JOHN TOWNSEND, Hastings, N.H. Filed Feb. 27, 1903. Serial No. 85,988. (No model.)

Claim.—1. In a dumping-wagon, the combination of a transversely-movable bottom adapted to open or close the bottom of the box as it is operated, two bolsters upon which said bottom is supported, means located at each bolster and connected with the bottom whereby it may be moved transversely to open and close the same, and reaches connecting the bolsters, said reaches being separated, substantially as described.

2. In a dumping-wagon, the combination of a transversely-movable bottom adapted to open or close the bottom of the box as it is operated, means connected with the bottom whereby it may be moved transversely and returned to its original position, and bolsters upon which the bottom is supported, reaches connecting the bolsters, said reaches being separated so that the space between them shall be as wide as the opening in the box, substantially as described.

3. In a dumping-wagon, the combination of a transversely-movable bottom adapted to open or close the bottom of a box, bolsters upon which the bottom is supported, reaches connecting the bolsters consisting of tubes; shafts traversing the tube reaches and journaled in the bolsters, spur-gearing upon the shafts, and racks upon the movable bottom, and means for actuating the shafts to rotate them in either direction, substantially as described.

4. The combination of a wagon, gearing consisting of two axles and wheels and fixed bolsters mounted upon the rear axle, a rocking, swiveling

bolster mounted upon the front axle, reaches connecting the front and rear bolsters, said reaches being separated a distance equal to, or more than one-third of the width of the wagon, a king-bolt connecting the front bolster and front axle and diverging braces ending below the front axle and passing upwardly and rearwardly and fixedly connected to the reaches, substantially as described.

5. The combination of a wagon, gearing consisting of two axles and wheels, and fixed bolsters mounted upon the rear axle, a rocking swiveling bolster mounted upon the front axle, reaches connecting the front and rear bolsters, said reaches being separated a distance equal to or more than one-third of the width of the wagon, a king-bolt connecting the front bolster and front axle, and diverging braces ending below the front axle and passing upwardly and rearwardly and fixedly connected to the reaches, and a hemispherical bearing between the bolster and the front axle, and centrally traversed by the king-bolt, substantially as described.

700,581. SNAP-HOOK. ALBERT J. TOWNE, Santa Ana, Cal. Filed Mar. 7, 1903. Serial No. 87,554. (No model.)

Claim.—1. An improved snap-hook of the class described, comprising two hooks or jaws having flat cheeks which are placed in contact, an eccentric arranged in a corresponding opening in one of the cheeks and having transverse as specified, and a strap-loop which is rotatably connected with one of said transverse and rigidly connected with the other, substantially as shown and described.

2. The improved snap-hook of the class described, composed of two hooks having flat cheeks, one of which is provided with a lengthwise slot and a circular opening, a pivot passing through said slot and the opposite hook, and an eccentric disk arranged in the said circular opening and having transverse one of which extends through and is rotatable in the opposite cheek, and a strap-loop which is rotatably connected with one of said transverse and rigidly connected with the other, whereby, when said loop is thrown upward from the normal position, the said hooks are separated in the manner shown and described.

3. An improved snap-hook of the class described, composed of two jaws or hooks proper, which are pivotally connected, and an eccentric which is applied to the cheeks below the said pivot, and a strap-loop rigidly connected with one of the transverse of said eccentric, substantially as shown and described.

4. The eccentric attachment for a twin snap-hook consisting of a disk having transverse arranged eccentrically, and aligned as shown and described, whereby the device is adapted for operation in connection with hooks and a strap-loop in the manner specified.

700,582. TRIP-SUPPORT FOR HORNS OF TALKING-MACHINE. LOUIS F. VALLENTINE, New York, N. Y., assignor to Universal Talking Machine Manufacturing Company, New York, N. Y., a Corporation of New York. Filed Mar. 13, 1903. Serial No. 88,584. (No model.)

Claim.—1. In a horn-supporting apparatus for talking-machines, the combination of the vertically-extending standard or support and base therefor, the horn-supporting fork, the swinging arm pivoted on said support and adapted to carry the sound-box and small end of the horn on the inner end, the right arm extending from the upper portion of the support and means for attaching the other end of said right arm to a talking-machine case.

2. In a horn-supporting apparatus for talking-machines, the combination of the vertically-extending standard or support and base therefor, the horn-supporting fork, the swinging arm pivoted on said support and adapted to carry the sound-box and small end of the horn on the inner end, the right arm extending from the upper portion of the support and means for attaching the other end of said right arm to a talking-machine, said standard being vertically extensible.

3. In a horn-supporting apparatus for talking-machines, the combination of the vertically-extending standard or support and base therefor, the horn-supporting fork, the swinging arm pivoted on said support and adapted to carry the sound-box and small end of the horn on the inner end, the right arm extending from the upper portion of the support and means for attaching the other end of said right arm to a talking-machine case, said standard, swinging arm and right arm being all adjustable lengthwise.

4. In a horn-supporting apparatus for talking-machines, the combination of the vertically-extending standard or support and base therefor,

the horn-supporting fork, the swinging arm pivoted on said support and adapted to carry the sound-box and small end of the horn on the inner end, the right arm extending from the upper portion of the support and means for attaching the other end of said right arm to a talking-machine case, said right arm having a hinged connection to the vertical standard, whereby the same may be folded together when the arm is detached from the talking-machine case.

5. In a horn-supporting apparatus for talking-machines, the combination of the vertically-extending standard or support and base therefor, the horn-supporting fork, the swinging arm pivoted on said support and adapted to carry the sound-box and small end of the horn on the inner end, the right arm extending from the upper portion of the support and means for attaching the other end of said right arm to a talking-machine case, said standard, swinging arm and right arm being all adjustable lengthwise and detachably connected together.

700,583. AXLE-BEARING. THOMAS F. VAN LUYK, Oshkosh, Wis., assignor of one-half to Thomas George Hurley, Oshkosh, Wis. Filed Aug. 21, 1902. Serial No. 73,708. (No model.)

Claim.—1. The combination of a rotary axle having two collars G, G' thereon, an axle-box H having transverse F at right angles to said axle, a series of rollers F surrounding said axle between the collars thereof and rolling upon the interior surface of said axle-box, a series of balls M surrounding the axle exterior to one of said collars, a metallic washer J on the other side of the balls closing the recessway thereof and forming a thrust-bearing for said shaft, a thick resilient washer K surrounding the axle outside of the washer J and forming both a dust-excluding means and a resilient support for said washer J, an annular disk L curved into the outer end of said axle-box to clamp said washers in place, and a pedestal having a pair of sheet-plates A, A' in which said transverse are mounted.

2. An axle-bearing comprising a rotary axle having a journal, a pair of collars spaced apart upon and carried by said journal, an axle-box having a cylindrical inner flange surrounding said journal, a series of cylindrical rollers forming bearings between said journal and said axle-box and confined by said collars, a series of balls surrounding said journal exterior to one of said collars, a metallic annular disk on the opposite side of said balls closing the recessway thereof, a resilient packing outside of said disk, and means for confining said resilient packing in said axle-box, whereby said packing forms substantially a dust-excluding means around said journal and a springing support for said bearing-disk.

3. An axle-bearing comprising a rotary axle having a journal, a pair of collars spaced apart upon and carried by said journal, an axle-box having a cylindrical inner flange surrounding said journal, a series of cylindrical rollers forming bearings between said journal and said axle-box and confined by said collars, a series of balls surrounding said journal exterior to one of said collars, a metallic annular disk on the opposite side of said balls closing the recessway thereof, a resilient packing outside of

said disk, and an annular disk screw-threaded into the outer open end of said bearing-box, whereby to retain said bearing-disk and resilient packing in place, substantially as described.

700,584. BAKING-CUP CLEANER. MARCEL VAUTOUR and HERMAN FRIEDSTADT, Fishersville, Mass. Filed Apr. 30, 1901. Serial No. 87,957. (No model.)

Claim.—1. In a device for cleaning baking-cups, the combination of a vertical spindle, a cleaning-head comprising a support on the upper end of said spindle, with scraping blades or knives pivotally connected at their upper ends thereto, a wire extending from each scraping blade or knife through the spindle, a spring tending to throw each blade or knife outwardly, a stop on each of said wires for limiting the outward motion of its knife, and means for rotating the spindle.

2. In a device for cleaning baking-cups, the combination of a socket a spring-supported spindle having a spiral groove, a pin or screw engaging the groove, and a cleaning-head mounted on the end of said spindle, and comprising a support, cleaning blades or knives pivoted at their upper ends thereto, a guide-wire extending from each cleaning blade or knife through the spindle, a spring mounted on each of said guide-wires tending to swing its blade or knife outwardly, and a stop on each of the guide-wires for limiting the outward motion of its cleaning blade or knife.

700,585. ELECTRIC ALARM. BERN VIAL, Fils, Lyons, France.
Filed July 31, 1901. Serial No. 70,331. (No model.)

Claim.—A circuit-closing device, consisting of two contact-pieces, one above the other, a washer of conducting material supported on the lower contact-piece, and a compound pendulum suspended from the upper contact-piece, the upper member of said pendulum being made of conducting material and passing through said washer and the lower member being connected thereto below the washer, substantially as set forth.

700,586. MAIL-MARKING MACHINE. HENRY E. WATTS, Boston, Mass. Filed Jan. 12, 1902. Serial No. 80,414. (No model.)

Claim.—In a mail-marking machine, a member of a printing-couple yieldingly held out of printing position, means for intermittently and positively moving said member into printing position when no letter is passing, and letter-controlled means to lock said member in printing position.

700,587. COMBINED CAP-VEIL AND EYE-CHIELD. HARRY L. WALKER, Providence, R. I., assignor of one-half to Walter H. Brown, Inghild and Charles H. Lawton, Freetown, R. I. Filed Feb. 21, 1902. Serial No. 80,008. (No model.)

Claim.—1. The combination with a cap, of a visor, an eye-chield consisting of lenses and a frame with horns or projections from its two upper corners, and a metallic lining-plate attached to said visor and provided with bent slotted ears with which said horns or projections of the eye-chield are engageable, substantially as shown.

2. The combination with a cap, of a visor, an eye-chield consisting of lenses and a frame with horns or projections, and a metallic lining-plate attached to said visor and having integral bent slotted ears with which said horns or projections of the eye-chield are engageable, substantially as described.

3. The combination with a cap, of a visor, an eye-chield consisting of lenses and a frame with horns or projections, and a metallic lining-plate attached to said visor and provided with a hook on its inner edge and

with two bent slotted ears on its opposite ends with which ears, respectively, said horns or projections are engageable, substantially as specified.

4. The combination with a cap, of a visor, an eye-chield consisting of lenses and a frame with horns or projections and a metallic lining-plate attached to said visor and provided with an integral hook on its inner edge and with two integral bent slotted ears on its opposite ends with which ears, respectively, said horns or projections are engageable, substantially as set forth.

5. In combination with a cap, a visor, an eye-chield consisting of lenses and a frame having two horns or projections which are rectangular in cross-section, and a metallic lining-plate attached to said visor and provided with two bent earpieces at its opposite sides, each of which earpieces has a slot which in its inner part is straight and of a width slightly in excess of the thickness of said horns or projections and in its outer part is adapted to allow said horns or projections to turn therein ninety degrees, substantially as shown.

6. In combination with a cap, a visor, an eye-chield consisting of lenses and a frame with horns or projections, said two guides adapted to allow said horns or projections first to slide and then to partially turn therein, and provided with locking means adapted to prevent the swinging of said eye-chield when in its wearing position, substantially as described.

700,588. TRUNK. BRAINE WALSH, Lonsington, N. Y. Filed Feb. 2, 1902. Serial No. 80,308. (No model.)

Claim.—1. A trunk provided with a body, a slidable drawer arranged to be drawn through the front of the body, and cushion-blocks of resilient material secured directly to the closed back portion of the drawer, on the outside thereof, and adapted to strike against the solid back part of the trunk-body, said cushion-blocks extending practically from the bottom to the top edge of the drawer and said blocks at opposite corners of the drawer being of uniform thickness.

2. As a new article of manufacture, a trunk provided with slidable drawers, each having a bottom secured across the exposed front thereof, the drawer-front and the bottom having recesses formed in their opposing faces and adapted to produce concealed handholds.

3. As a new article of manufacture, a trunk comprising a body having a hinged cover and a series of solid partitions forming a series of compartments, drawers fitted in certain compartments and having recessed fronts, recessed bottoms secured to the drawer-fronts across the recesses therein, other bottoms fastened to the outside of the trunk in alternate relation to the partitions therein and in coincident position to the bottoms of the drawers, covers for said drawers, and buffers attached to the inner corners of the drawers.

700,589. GAME. ELMER E. WHEAT, Whittier, N. J. Filed Apr. 5, 1901. Serial No. 80,567. (No model.)

Claim.—1. A game apparatus comprising a separable box or scoop (A) having holes through a wall thereof, and a page (B) adapted to be thrust through

the holes, and a freely-moving object within the box, said object having holes therein adapted to engage one of the page.

2. A game apparatus comprising a two-part separable box having perforations through the outer wall thereof, indicating characters made adjacent to the perforations and wholly on the inside of the box so as not to be seen from without, and a series of removable page adapted to be thrust through the holes.

700,590. **BIKYLE.** HENRY C. WHEAT, Buffalo, N. Y. Filed Mar. 1, 1901. Serial No. 48,457. (No model.)

Claim.—1. A bicycle comprising a front wheel, a rigid frame having a horizontal lower rear brace A^1 , the rear brace or fork A^2 , having its ends extended in alignment and constituting journals, sprocket-wheels mounted on said journals, corresponding front sprocket-wheels, a transverse front shaft B , journaled in the front portion of the frame, endless traveling tracks running on the rear sprocket-wheels, the rear running wheel journaled in the rear fork above the lower brace, and a gear connection between each running wheel and one of the rear sprocket-wheels, substantially as shown and described.

2. A bicycle comprising a rigid frame having a lower brace, a front wheel, a rear wheel, a rear fork journaled on lower brace, the rear wheel journaled in each rear fork above the fulcrum, means for holding the rear fork in any forward-and-back adjustment, sprocket-wheels mounted on journals formed on the lower ends of the rear fork, a front shaft and sprocket-wheel therein, endless tracks running on the sprocket-wheels, and gearing connecting the rear wheel and tracks, substantially as shown and described.

3. A bicycle comprising a frame which is fulcrumed on the front axle, and the rear fork or middle-post, which is adjustable forward and back and fulcrumed at the rear end of the steered frame, the rear wheel journaled on the mid fork at a point above its fulcrum, and having a pinion on its axle, a gear-wheel meshing with the said pinion and having its axle coincident with the fulcrum of the rear fork, a shaft H arranged transversely between the running wheels, and endless tracks running on sprocket-wheels arranged on said shaft and other sprocket-wheels journaled on the rear fork, substantially as shown and described.

700,591. **ICE-CREAM FRITTER.** ROBERT E. C. WHEAT, New York, N. Y. Filed June 10, 1901. Serial No. 48,500. (No model.)

Claim.—1. The combination of a longitudinally-revoluble vessel, a cream-can suspended in the same having a closed bottom and an open top, an ice-receptacle surrounding the bottom and sides of the cream-can and revoluble therewith, openings provided with covers in the ends of the exterior vessel one of which gives access to the ice-receptacle and the other to the cream-can—the cover of the latter opening consisting of an exterior annular part, a perforated center part and packing-rings between

the two parts of the cover—a rotatable rod passed down through the perforation in the center part of the cover and adapted to be rotated independently of the cover, disks secured on the rod against the upper and under sides of the two parts of the cover that rotate with the rod, and scrapers connected with the rod in the cream-can, substantially as specified.

2. In an ice-cream freezer the combination of a frame, an exterior revoluble vessel provided with transverse pivots that rest in bearings in the said frame and on which the said vessel is revolved, a cream-can having a closed bottom and open top and right-angled flanges projected from the top and fastened to the side walls of the exterior vessel near one end thereof, an ice-receptacle surrounding the bottom and sides of the cream-can, screw-threaded openings in the ends of the vessel one of which gives access to the ice-receptacle and the other to the cream-can, a flanged screw-threaded cover for the opening into the ice-receptacle, a cover for the opening over the cream-can consisting of an annular part and a center perforated part—the outer periphery of the annular part being screw-threaded and the inner periphery grooved—and the outer periphery of the center part also grooved, packing-rings fitted into the grooves of the center and annular parts and bearing against each other, a screw-threaded rotatable rod provided with a handle passed down into the cream-can through the perforation in the center plate of the cover, and clamping-disks secured on the said rod against the upper and under sides of the cover, and scrapers and dashers connected with the said rotatable rod inside of the cream-can, substantially as specified.

3. In ice-cream freezer a cover for the opening into the cream-can consisting of an annular part having its outer periphery screw-threaded and its inner periphery grooved, a perforated center part having its outer periphery grooved, packing-rings in the grooves of the center and annular parts that bear against each other, a screw-threaded rod passed through the perforation in the center part and clamping-disks secured on the rod against the upper and lower sides of the center part, packing-rings and annular part of the cover, substantially as specified.

4. In an ice-cream freezer the combination with the cream-can of a cover consisting of an annular part having its outer periphery screw-threaded and its inner periphery grooved, a perforated center part having its outer periphery grooved, packing-rings in the adjoining grooves of the center and annular parts that bear against each other, a two-part screw-threaded rotatable and detachable rod passed down into the cream-can through the perforation in the cover, disks secured to the upper part of the rod against the upper and lower sides of the cover, cream-arms connected with the lower part of the rod, scrapers connected with the ends of the cream-arms adjacent to and parallel with the walls of the cream-can and dashers connected directly with the lower part of the rod, substantially as specified.

700,592. **REVOLVER-FIREARM.** WILLIAM J. WHITING, Haverhill, near Birmingham, England. Filed May 27, 1901. Serial No. 48,108. (No model.)

Claim.—1. In a revolver, the combination with a removable cylinder provided with recesses, of a cylinder-locking catch adapted to en-

curatively engage said recess, and a hand-operated pusher for acting on said catch to disengage mine from the said cylinder-recess, substantially as set forth.

2. In revolver-firearm; the combination with a removable cylinder having a series of peripheral recesses, of a spring-catch adapted to successively engage said recesses, and a pusher working through the barrel-chamber of the revolver and acting upon said catch for the purpose of disengaging the same from the said cylinder-recesses, substantially as herein described and also as set forth.

3. In revolver-firearm; the combination with a cylinder-locking catch; of a cylinder-alignment device, and a means for disengaging both catches simultaneously from the cylinder, substantially as herein described and also as set forth.

4. In automatic revolver-firearm; the combination with a cylinder having a series of peripheral recesses alternating with forward channels, of a catch and lock-work mechanism acting both as a cylinder-lock and a direction device, a second catch for retaining the cylinder in alignment with the barrel when the barrel is opened, and a means for simultaneously disengaging both catches from the cylinder, substantially as herein described and also as set forth.

5. In revolver-firearm; the combination with a cylinder, having peripheral recesses, of a combined cylinder lock and alignment device, which automatically engages with one of the said recesses of the cylinder when the revolver is opened, but is lifted out of such engagement when the revolver is closed, the same also being provided with a pusher-releasing means arranged and acting substantially in the manner herein described.

6. In revolver-firearm; the combination with a cylinder locking and alignment device, of a cylinder provided with a series of separated lugs, successively engaging with a recess, sinking or shoulder on the under side of the barrel-chamber, for the purpose of preventing the withdrawal of the cylinder, substantially as herein described and also as set forth.

700,593. LOOM-REED. RICHARD WILSON, Darmstadt, Germany. Filed Aug. 18, 1901. Serial No. 73,305. (No model.)

Claim.—1. A reed having at one end transposed rows of dents, and separate bridges made to respectively engage or unite each row, said dents being transposed or separated to such an extent that throughout a portion of the reed a space is formed between the dents in the plane of the reed so as to allow the warp-threads in this part to lie free at one side of each dent and thereby prevent compression and consequent friction of the threads, substantially as described.

2. A reed having at one end transposed rows of dents, and separate bridges made to respectively engage or unite each row, said dents being transposed or separated to such an extent that throughout a portion of the reed a space is formed between the dents in the plane of the reed so as to allow the warp-threads in this part to lie free at one side of each dent and thereby prevent compression and consequent friction of the threads said dents being arranged in rows to insure diminished friction and allow narrowing of the contracted ends of trapezoidal reeds, substantially as described.

700,594. ROAD-SCRAPER. THOMAS WILSON, Meyers Falls, Wash. Filed Aug. 9, 1901. Serial No. 71,472. (No model.)

Claim.—1. The combination of the scraper-blade, a main and an auxiliary draft-beam, means for connecting the auxiliary beam to the main beam, and means for connecting the rear of the auxiliary draft-

beam at different points along the blade, whereby to adjust the said auxiliary beam transversely of the direction of draft.

2. The combination of the scraper-blade, a main draft-beam connected therewith, an auxiliary draft-beam, means for connecting the forward end of the auxiliary draft-beam with the main beam at different points along the main beam, and means for connecting the rear end of the auxiliary draft-beam with the blade at different points along the blade, whereby to adjust said rear end transversely of the direction of draft.

3. In road-scraper, the combination, with a blade or shovel, handle connected therewith, draft device located at the ends of the blade or shovel, a main draft-beam connected with the draft device at one end of the blade or shovel, and an auxiliary draft-beam having adjustable connection with the main draft-beam and a connection with the draft device at the opposite end of the main blade or shovel, for the purpose set forth.

4. In road-scraper, the combination, with a main blade or shovel, handle attached thereto, and draft device located at the ends of the said main blade or shovel, of an auxiliary draft device connected with the main blade or shovel, an auxiliary or extension blade or shovel, attached at one end to the main blade or shovel, a main draft-beam connected with one end of the main blade or shovel and an auxiliary draft-beam having adjustable connection with the main draft-beam and with the auxiliary draft device carried by the main blade or shovel, for the purpose set forth.

5. The combination of a scraper-blade, a main draft-beam connected with one end of the blade, an auxiliary draft-beam connected with the main beam, a connection for the auxiliary draft-beam and blade at that end of the blade opposite to that with which the main draft-beam is connected, and a second connection for the auxiliary beam and the blade at a point intermediate the ends.

700,595. BARNETT-STRETCHER. JOHN H. YOUNG, East Troy, Pa. Filed July 18, 1901. Serial No. 63,746. (No model.)

Claim.—1. A tresser stretcher and crupper comprising an extendible under frame made in two parts held together by elastic straps, a flexible upper frame made in two parts joined together by hinges, coupling devices at the ends of said frames whereby the frames are joined together and at the same time the ends of the tressers are clamped therebetween, and clamping devices at the sides.

2. A tresser stretcher and crupper comprising an extendible under frame in two parts united by elastic connections, a flexible upper frame, eyes projecting upward from the ends of the under frame, pins to engage said eyes at the ends of the upper frame, and clamping devices at the sides.

700,596. MILK-CAN. OLA E. ARLAND, St. Paul, Minn. Filed June 20, 1900. Serial No. 731,308. (No model.)

Claim.—1. The combination with a milk-can of a cover having a handhold secured to its upper side, and a milk-measure secured to its under side; said measure being adapted to enter entirely down into the neck of the can, and having a flaring top, and near its bottom end enlarged to fill the neck of the can.

2. The combination with a milk-can, of a cover closing the neck of the can and having a handle at its upper side and a milk-measure secured with its bottom end to the under side of the cover, and adapted to enter into the neck of the can; said measure having a hollow guard all around upon its outer side to receive any milk running from the edge toward the bottom end of the measure, substantially as shown and described.

700,597. APPARATUS FOR ELECTRICALLY WINDING UP DRIVING-SPRINGS. HENRIK LARSEN, Christiansburg, Germany. Filed Feb. 22, 1901. Serial No. 74,328. (No model.)

Claim.—1. In an apparatus for electrically winding up driving-springs, the combination with an electromagnet, of an armature arranged to swing between the magnet-poles, a contact pin or stud movable with said armature, a tilting device or lever making and breaking electrical contact with the said stud, a driving-spring arranged to be placed under tension by the movement of said armature when the latter is attracted by the said magnet; and a controlling device or stud, moving with said armature, for assisting the tilting motion of the said tilting device or lever, and for keeping the same from being thrown back by sparking, substantially as and for the purpose set forth.

2. In an apparatus for electrically winding up driving-springs, the combination, with an electromagnet, of an armature arranged to swing between the magnet-poles, a contact pin or stud movable with said armature, a tilting device or lever making and breaking electrical contact with the said stud, a driving-spring arranged to be placed under tension by the movement of said armature when the latter is attracted by said magnet, a controlling-stud movable with said armature, and an insulating-roller carried by said stud to strike the tilting lever for assisting its tilting motion and for keeping the same from being thrown back by sparking, substantially as and for the purpose set forth.

700,598. PRIMARY BATTERY. WILLIAM H. BATE, Louisville, Ky., assignor to Scott's American Electric Co., Louisville, Ky., near Paris, France. Filed Mar. 21, 1901. Serial No. 63,180. (No model.)

Claim.—1. In a galvanic cell, the combination with the inner vessel of a cover having an internal annular recess adapted to receive the edge of said inner vessel, said cover moreover comprising an external annular frame, having an internal lip thereon over which said edge can be folded, and insulating winding material for securing said inner vessel within said annular frame, substantially as described.

2. In a galvanic cell, the combination of a detachable cover, the inner porous vessel connected to said cell, of a collar on the upper part of the casing of the cell, of an interrupted screw-thread on said collar, of a ring on said cover, of an interrupted screw-thread on said ring adapted to engage with the said screw-thread on the collar, of a packing-ring carried by said collar, of a shoulder on said cover adapted to bear against said packing-ring, and of means for retaining the interrupted screw-threaded ring in its closed position, for the purpose specified.

3. In a galvanic cell, the combination of a detachable cover, an internal lip thereon, an inner porous vessel or chamber in the form of a cone, a neck or casing containing one of the electrodes, means for tightly securing the upper part of said neck or casing to the lip on the cover, a collar on the outer casing of the cell, of an interrupted screw-thread on said collar, a ring on said cover, an interrupted screw-thread on said ring, a packing-ring carried by said collar and a shoulder on said cover adapted to bear against said packing-ring, and of means for retaining the interrupted screw-threaded ring in its closed position, for the purpose specified.

4. In a galvanic cell, the combination of a detachable cover, an internal lip thereon, an inner porous vessel or chamber in the form of a cone,

neck or casing containing one of the electrodes, means for tightly securing the upper part of said neck or casing to the lip on the cover, a collar on the outer casing of the cell of an interrupted screw-thread on said collar, a ring on said cover, an interrupted screw-thread on said ring, a packing-ring carried by said collar, a shoulder on said cover adapted to bear against said packing-ring, corrugations on said cover, and a clip on said outer casing of the cell adapted to engage with said corrugations, substantially as and for the purpose specified.

5. In a galvanic cell, the combination with the detachable cover, the inner porous vessel or chamber the means for securing the upper part of said porous vessel or chamber to the cover and the means for hermetically but detachably connecting the cover to the outer casing of the cell; of an internal projection on the bottom of said outer casing of the cell, and of a block of insulating material at the bottom of the inner porous vessel or chamber said block having a recess for the reception of said internal projection, substantially as and for the purpose specified.

700,599. SHIFTING DEVICE FOR PIER, &c. WILLIAM D. BALDWIN, New York, and AUGUST BUNN, Yonkers, N. Y., assignors to Otto Elevator Company, East Orange, N. J., a Corporation of New Jersey. Filed Dec. 17, 1901. Serial No. 80,322. (No model.)

Claim.—1. The combination with a capstan arranged above the footway of a pier or embankment, and with a shaft extending downward into a vault below the footway, of a motor adapted to rotate in one direction, a pair of driving-pulleys upon the shaft of the motor, a driving-disk carried by the shaft of the capstan, means for shifting the pulleys to bring one or the other into engagement with the disk, and control devices for regulating the speed and stopping and starting the motor and for shifting the pulleys, substantially as set forth.

2. The combination with the footway of a pier or embankment, of a capstan arranged above the same, a shaft extending through the footway to a vault below the same and provided with a driving-disk, a motor adapted to rotate in one direction, driving-pulleys driven therefrom and adapted to be shifted alternately into and out of engagement to drive the said disk, a control device for stopping and starting and regulating the speed of the motor having an operating device above the footway, a brake device, means extending above the footway for shifting the driving-pulleys, and connections between said means and the brake device, substantially as set forth.

3. The combination with the footway of a pier or embankment, of a capstan, driving-disk, motor, pulleys driven from the motor and adapted to be alternately brought into action to drive the disk in opposite directions, means for shifting the pulleys extending to the footway, a brake device, and connections between the brake device and the means for shifting the pulleys, substantially as set forth.

700,600. SHIFTING DEVICE FOR PIER, &c. WILLIAM D. BALDWIN, New York, and AUGUST BUNN, Yonkers, N. Y., assignors to Otto Elevator Company, East Orange, N. J., a Corporation of New Jersey. Filed Dec. 17, 1901. Serial No. 80,324. (No model.)

Claim.—1. The combination with a capstan, of a shaft secured thereto and extending downward into a vault or chamber, a friction-drum on said shaft, a driving-engine having a shaft carrying a friction-pinion, and means for shifting the position of the engine to carry the friction-pinion into and out of engagement with said drum, substantially as set forth.

2. The combination with a capstan, of a shaft extending downward

therefrom and carrying a friction-drum, a motor carrying a friction-pinion, said motor being pivotally supported to swing the pinion away from the drum, and means for swinging the motor to bring the pinion into engagement with the drum, substantially as set forth.

2. The combination with a capstan, of a shaft extending downward therefrom and carrying a friction-drum, a motor carrying a friction-pinion, said motor being pivotally supported to swing the pinion away from the drum, means for swinging the motor to bring the pinion into engagement with the drum, and a control device adjacent to the capstan to operate said means, substantially as set forth.

4. The combination with a capstan, of a shaft secured thereto and extending downward into a vault or chamber, a friction-drum on said shaft, an electric driving-engine having a shaft carrying a friction-pinion, and an electric motor for shifting the position of the engine to carry the friction-pinion into and out of engagement with said drum, substantially as set forth.

5. The combination with a capstan, of a shaft secured thereto and extending downward into a vault or chamber, a friction-drum on said shaft, an electric driving-engine having a shaft carrying a friction-pinion, an electric motor for shifting the position of the engine to carry the friction-pinion into and out of engagement with said drum, a series of switches, and a control device adjacent to the capstan for operating said switches, substantially as set forth.

6. The combination with a capstan, of a shaft secured thereto and extending downward into a vault or chamber, a friction-drum on said shaft, an electric driving-engine having a shaft carrying a friction-pinion, an electric motor for shifting the position of the engine to carry the friction-pinion into and out of engagement with said drum, a series of switches, and control devices adjacent to the capstan for operating said switches, substantially as set forth.

7. The combination with a shaft supporting a capstan at one end and carrying a friction-drum, of an electric-motor engine having a shaft carrying a friction-pinion and movable to and from said drum, an electric motor for shifting the engine, a reversing-switch, an electric motor for shifting said switch, and means for operating the switch-controlling motor from different positions adjacent to the capstan, substantially as set forth.

8. The combination with a shaft supporting a capstan at one end and carrying a friction-drum, of an electric-motor engine having a shaft carrying a friction-pinion and movable to and from said drum, an electric motor for shifting the engine, a control device for stopping, starting and reversing the engine, an electric motor for actuating the control device, and means for putting the control-device motor into and out of operation from different points adjacent to the capstan, substantially as set forth.

9. The combination of a capstan, shaft, friction-gears, movable electric engine, electric motor for shifting the engine and controlling the passage of current thereto, and a brake connected to the engine to be released as the gears are brought into engagement, substantially as set forth.

10. The combination with a capstan, motor-engine, gear, and electric control device, of solenoids and cores connected to actuate the control device, and means adjacent to the capstan for making and breaking at will circuits including the solenoids, substantially as set forth.

11. The combination with a capstan, motor-engine, gear, and electric control device, of solenoids and cores connected to actuate the control device, a brake and solenoid for operating the same, and means adjacent to the capstan for making and breaking at will circuits including the solenoids, substantially as set forth.

12. The combination with a capstan, movable engine, gear, control device, and electric motor for shifting the engine and actuating the control device, of a plurality of circuit-breakers arranged adjacent to the capstan to make and break the circuits including the said motor, substantially as set forth.

13. The combination with a capstan, shaft, friction-drum, movable engine, and friction-pulley, of a solenoid having a core connected to the engine, and a brake device connected with the parts operated from said solenoid, substantially as set forth.

700,601. COMBINATION-GARMENT. GEORGE KALSHOF, Weimar, Germany. Filed Dec. 18, 1900. Serial No. 40,364. (No model.)

Claim.—1. A combination-garment consisting of a shirt and trousers, the shirt having a false front to simulate a coat or jacket, a tailpiece connected to the back of the garment made to represent the tail of a coat or jacket, and a belt to surround the garment, substantially as set forth.

2. A combination-garment consisting of a shirt and trousers, the shirt having a false front to simulate a coat or jacket, and a tailpiece detachably connected to the back of the garment and made to represent the tail of a coat or jacket.

700,602. PROCESS OF MAKING DETERGENT. GEORGE BARR, Leeds, England. Filed Sept. 12, 1901. Serial No. 78,598. (No specimen.)

Claim.—1. A process of manufacturing a detergent powder consisting in mixing olein and a suitable cereal, then adding caustic alkali of suitable strength, and then exposing said mass to the atmosphere until the free alkali becomes carbonated.

2. A process of manufacturing a detergent powder consisting in mixing in water olein and a cereal, adding an alkali thereto, and then exposing the mass to the atmosphere for the purpose set forth.

3. A process of manufacturing a detergent powder consisting in thoroughly mixing a suitable cereal and olein, then adding to the mixture and thoroughly incorporating therewith caustic alkali, and then suitably exposing the mixture to the atmosphere.

4. A process of manufacturing a detergent powder consisting in suitably mixing oatmeal and olein, then adding to the mixture and thoroughly incorporating therewith caustic alkali of a sufficient strength, and then suitably exposing the mixture to the atmosphere until the free alkali becomes carbonated.

5. A process of manufacturing a detergent powder consisting of mixing olein and oatmeal together, incorporating in the said mixture an alkali, and then exposing said mass to the atmosphere, for the purpose set forth.

700,603. FIRE-EXTINGUISHER. WILLIAM H. BARTON, Boston, Mass. Filed Oct. 24, 1901. Serial No. 78,562. (No model.)

Claim.—1. In a fire-extinguisher, a shell or case having a cover and containing a cage, combined with a bottle supported by said cage provided at its outlet with a valve-out, a valve-plate freely movable toward and from its seat, and a support for said valve-plate attached to the neck or end of said bottle, substantially as described.

2. In a fire-extinguisher, a shell or case having a cover and containing a cage, combined with a bottle supported by said cage, a tubular slip-throat into the outlet of said bottle formed or provided at its extremity with a valve-out, and supported by a plate *f*, resting on the bottle, a disk movable toward and from said seat and means attached to said plate for supporting and guiding said disk, and means for attaching said plate to the bottle, substantially as described.

3. In a fire-extinguisher, a shell or case having a cover and containing a cage, combined with a bottle supported by said cage provided at its outlet with a valve-out, a valve-plate therefor, and a valve-plate support attached to said bottle having guides for supporting and guiding said valve-plate, substantially as described.

4. In a fire-extinguisher, a shell or case having a cover and containing a cage, combined with a bottle supported by said cage provided at its outlet with a valve-out, a valve-plate therefor, and valve-plate support attached to said bottle having guides on which said valve-plate slides, substantially as described.

5. In a fire-extinguisher, a shell or case having a cover and containing a cage, combined with a bottle supported by said cage provided at its outlet with a valve-out, a valve-plate therefor, and a valve-plate support attached to said bottle having means for limiting the movement of the valve-plate away from its seat, substantially as described.

6. In a fire-extinguisher, a shell or case having a cover and containing a cage, combined with a bottle supported by said cage provided at its outlet with a valve-out, a valve-plate freely movable toward and from its seat, and a support for said valve-plate having a plurality of spring-actuating flaps which clip over a lip on the end of the bottle, substantially as described.

7. In a fire-extinguisher, a shell or case having a cover and containing a cage, combined with a bottle supported by said cage provided at its outlet with a valve-out, a valve-plate freely movable toward and from its seat, and a support for said valve-plate having a plurality of spring-actuating flaps which clip over a lip on the end of the bottle, substantially as described.

8. In a fire-extinguisher, a shell or case having a cover and containing a cage, combined with a bottle supported by said cage provided at its outlet with a valve-out, a valve-plate freely movable toward and from its seat, and a support for said valve-plate having a plurality of spring-actuating flaps which clip over a lip on the end of the bottle, substantially as described.

9. In a fire-extinguisher, a shell or case having a cover and containing a cage, combined with a bottle supported by said cage, a tubular slip-throat into the outlet of said bottle formed or provided at its extremity with a valve-out, and formed integral with a plate *f* which rests on the end of the bottle, a disk movable toward and from said seat, guide-rods projecting from said plate which guide said disk and a clip supported by said rods for limiting the movement of said disk away from its seat, and a plurality of spring-actuating flaps on said plate which clip over the lip on the end of the bottle, substantially as described.

700,604. LOOSE-LEAF LEDGER. JAMES BARKER, Detroit, Mich. assignor to Charles F. Barker, Detroit, Mich. Filed May 31, 1901. Serial No. 40,364. (No model.)

Claim.—1. In a loose-leaf ledger, the combination with the top and bottom covers, of connecting-pieces intermediate the covers, a series of ledger-leaves loosely connected to the parts, and means for causing the sides of the leaves after their insertion within the ledger.

2. In a loose-leaf ledger, the combination with the top and bottom covers, of telescoping parts connecting the covers, a central guide at

each side of the ledger and intermediate the covers, and means for adjusting said guide transversely of the covers.

3. In a loose-leaf ledger, the combination with the top and bottom covers, connecting-pieces therebetween, a central guide at one side of the ledger, the guide members being adjustably secured to the upper and lower covers, respectively, and adjusting-screws revolved upon the covers for operating the guide.

4. In a loose-leaf ledger, the combination with the ledger-covers each having a plurality of threaded apertures formed therein in proximity to the rear edge, the apertures in one cover being of less diameter than the corresponding apertures in the complementary cover, of threaded plugs engaging within the apertures flush with the outer sides of the covers and projecting beyond the opposite inner sides, and tubular post-connections threaded upon the projecting portions of the plugs, the sections on one cover telescoping with the sections on the complementary cover.

700,605. SMOKE-CONSUMING FURNACE. CHARLES H. BARR, St. Louis, Mo. assignor of one-fourth to Matthias Gruber, St. Louis, Mo. Filed Dec. 12, 1901. Serial No. 58,595. (No model.)

Claim.—1. In combination with a furnace, a steam-pipe adapted to deliver steam to the combustion-chamber of said furnace, a normally closed valve in the steam-pipe, a pressure-meter for opening said valve provided with a constantly open exhaust-port, a reservoir having an inlet for fluid under pressure and an outlet in communication with the valve-meter, a door for the furnace and means act into operation by the opening of said door for bringing into communication, the inlet and the reservoir and cutting off communication between the reservoir and the pressure-meter and by the closing of the door for cutting off communication between the inlet and the reservoir and providing communication between the latter and the pressure-meter.

2. In combination with a furnace, a steam-pipe adapted to deliver steam to the combustion-chamber of said furnace, a normally closed valve in the steam-pipe, a pressure-meter for opening said valve provided with a constantly open exhaust-port, a reservoir having an inlet for fluid under pressure and an outlet in communication with the valve-meter, a reciprocating valve, a door for the furnace and means controlled by the opening of the door for moving said valve in one direction to bring into communication said inlet and said reservoir and out of communication between said reservoir and said pressure-meter, and by the closing of the door for moving said valve in the opposite direction to open communication between the reservoir and the pressure-meter and out of communication between the inlet and said reservoir.

3. In combination with a furnace, a steam-pipe adapted to deliver steam to the combustion-chamber of said furnace, a valve-stem, a normally closed valve in the steam-pipe and actuated by said stem on one end thereof, a diaphragm within a suitable housing and secured to the other end of said stem, and adapted to open said valve, a constantly open ex-

best-port in said housing, a reservoir having an inlet for fluid under pressure, and an outlet in communication with said housing, a door for the furnace and means actuated by the opening of said door for bringing into communication the inlet and the reservoir and cutting off communication between the reservoir and the housing, and by the closing of the door for cutting off communication between the inlet and the reservoir, and providing communication between the reservoir and the housing.

4. In combination with a furnace, a steam-pipe adapted to deliver steam to the combustion-chamber of said furnace, a normally closed valve in the steam-pipe, a pressure-motor for opening said valve provided with a constantly open exhaust-port, a reservoir having an inlet for fluid under pressure and an outlet in communication with the valve-motor, pressure-controlled means for bringing into communication said inlet and reservoir and cutting off communication between the reservoir and the pressure-motor, when water is admitted to said inlet and cutting off communication between said inlet and the reservoir and providing communication between the reservoir and the pressure-motor when water is cut off from said inlet, a valve for controlling admission of water to said inlet, a rock-shaft connected to said valve and cam-arm carried by said shaft, in line with the outward swing of the furnace-door.

700,606. MOLD FOR COLLAR-BUTTONS. JOHN E. BARRER, Detroit, Mich. Filed May 14, 1900. Serial No. 14,572. (No model.)

Claim.—1. In a two-part mold consisting of duplicate halves, a central longitudinal bar in each half in which are formed the gate and runners, bars in each half adjacent to said bar and having a series of recesses and grooves forming molds each connected with one of said runners, and means for clamping the two parts of the mold together.

2. In a two-part mold consisting of duplicate halves hinged together at one end, a series of sets of longitudinal mold-bars in each half, each set consisting of a central bar in which are formed a gate and runners, and bars at each side of said bar having a series of recesses forming molds, one opposite each of said runners, clamping-bars engaging the outer bars of each half of the mold, means for drawing said clamping-bars toward each other to clamp the mold-bars, and curved clamping-arms pivoted to one half of the mold and adapted to engage the other half to hold the faces of the mold in contact.

3. In a mold for irregular forms, a flask formed with a central longitudinal rib on the face of the cope portion thereof, and a corresponding rib on the drag; bars having recesses forming the molds, extending parallel with said ribs and at each side thereof; clamping-bars engaging the outer mold-bars and forming the sides of the cope and drag; rods secured to the clamping-bars at one side of said flask, extended through the mold-bars, the ribs, and the clamping-bars at the opposite side of the flask, and screw-threaded at their opposite ends; and crank-handles having internally-screw-threaded heads to receive the rods and engage the clamping-bars.

4. In a two-part mold, a series of longitudinal bars forming each half and provided with recesses forming the molds, and gate-bars longitudinally grooved to form gates and grooved laterally to form runners, a two-part flask to receive and hold said mold and gate-bars, and pins extending through said flask and engaging said gate-bars to raise the same above the surface of the mold and open the cast articles.

5. In a two-part mold, sets of longitudinal mold-bars forming each half of the mold, gate-bars longitudinally grooved to form gates adjacent to each set of mold-bars, a two-part flask adapted to receive said mold and gate bars, pins secured to the bottom of said gate-bars and extended through openings in the drag of the flask, a bar having recesses to receive the outer end of said pins, extending transversely across the drag, and levers pivoted to the drag to rotate said bar.

6. In a two-part mold, a flask consisting of a drag portion, means for rigidly supporting said drag in a position inclined from the vertical, a cope portion hinged to the drag at its lower end, clamping-bars on the cope and drag forming the sides of the flask and provided with transverse openings, curved clamping-arms pivoted to the drag at one end and provided with clamping-curves at their opposite ends to engage ribs on the cope and hold the halves of the flask together, and a mold portion consisting of central longitudinal ribs provided with transverse openings, on the drag and cope, sets of bars at each side of said ribs consisting of a central gate-bar longitudinally grooved to form a gate and provided with an elongated transverse opening, and mold-bars at each side thereof pro-

vided with transverse openings, rods secured at one end within the openings in said clamping-bars at the side of the flask and extended through the mold openings in said ribs, mold-bars, elongated openings in said gate-bars and the mold openings in the clamping-bars at the opposite side of said flask, crank-handles on the outer ends of said rods, pins secured at one end to the gate-bars and extended through the drag, transverse bars having recesses to receive the outer ends of said pins, and levers pivoted to the drag and adapted to operate the said pins.

700,607. SENDING APPARATUS FOR PNEUMATIC-DESPATCH SYSTEMS. ROBERT C. ROBINSON, Philadelphia, Pa. Filed July 31, 1901. Serial No. 70,366. (No model.)

Claim.—1. In a pneumatic-despatch system, a sender connected to a transmission-tube in combination with outer and inner gates adapted to open under the pressure of an inserted carrier, means for closing said gates when the carrier has passed them and means actuated by the insertion of a carrier into the sender for connecting the sender with an air-receptacle having substantially the pressure of the transmission-tube for the purpose of equalizing pressure on the inner gate.

2. In a pneumatic-despatch system, a sender connected to a transmission-tube in combination with outer and inner gates adapted to open under the pressure of an inserted carrier, means for closing said gates when the carrier has passed them, means actuated by the insertion of a carrier into the sender for connecting the sender with an air-receptacle having substantially the pressure of the transmission-tube for the purpose of equalizing pressure on the inner gate and means for admitting atmospheric pressure to the sender actuated by the passage of the carrier from the sender.

3. In a pneumatic-despatch system, a sender connected to a transmission-tube in combination with outer and inner gates adapted to open under the pressure of an inserted carrier, means for closing said gates when the carrier has passed them and means actuated by the insertion of a carrier into the sender for connecting the sender with the transmission-tube for the purpose of equalizing pressure on the inner gate.

4. In a pneumatic-despatch system a sender connected to a transmission-tube in combination with outer and inner gates adapted to open under the pressure of an inserted carrier, means for closing said gates when the carrier has passed them, means actuated by the insertion of a carrier into the sender for connecting the sender with the transmission-tube for the purpose of equalizing pressure on the inner gate and means for admitting atmospheric pressure to the sender actuated by the passage of the carrier from the sender.

5. In a pneumatic-despatch system, a sender connected to a transmission-tube in combination with outer and inner gates adapted to open

under the pressure of an inserted carrier, a valve mechanism arranged in one position to connect the sender with an air-receptacle having substantially the pressure of the transmission-tube and in another position to connect the sender with atmospheric pressure, means actuated by the insertion of a carrier into the sender to shift said valve to the first position and means actuated by the passage of the carrier from the sender to shift said valve to the second position.

6. In a pneumatic-despatch system, a sender connected to a transmission-tube in combination with outer and inner gates adapted to open under the pressure of an inserted carrier, a valve mechanism arranged in one position to connect the sender with an air-receptacle having substantially the pressure of the transmission-tube and in another position to connect the sender with atmospheric pressure, means actuated by the opening and closing of the outer gate in shift said valve to the first position and means actuated by the opening and closing of the inner gate to shift said valve to the second position.

7. In a pneumatic-despatch system, a sender connected to a transmission-tube in combination with outer and inner gates adapted to open under the pressure of an inserted carrier, means for closing said gates when the carrier has passed them, means actuated by the insertion of a carrier into the sender for connecting the sender with an air-receptacle having substantially the pressure of the transmission-tube for the purpose of equalizing pressure on the inner gate, means for admitting atmospheric pressure to the sender actuated by the passage of the carrier from the sender, and a restricted orifice in the atmospheric connection whereby the restoration of atmospheric pressure in the sender is made gradual.

8. In a pneumatic-despatch system, a sender connected to a transmission-tube in combination with outer and inner gates adapted to open under the pressure of an inserted carrier, means for closing said gates when the carrier has passed them means actuated by the insertion of a carrier into the sender for connecting the sender with an air-receptacle having substantially the pressure of the transmission-tube for the purpose of equalizing pressure on the inner gate, a lock for holding a gate closed out in operation by the passage of the carrier from the sender and a time-measuring device for withdrawing said lock.

700,608. SPACING ATTACHMENT FOR TYPE-WRITING MACHINES. BENJ. V. STARK, Boston, Mass. Filed July 16, 1900. Serial No. 24,706. (No model.)

Claim.—1. A type-writing machine having a plurality of keys each having a stroke of unvarying length, a paper-holding device, a feeding mechanism for causing the paper-holding device to be fed a single space, and means whereby the depression of any one of the keys may cause said paper-holding device to be fed a double space.

2. A type-writing machine having means controlled by each of the keys for causing the paper-holding device to be fed automatically a single or a double space at the will of the operator, by a variation in the period of depression of any one of the keys.

3. A type-writing machine having means for feeding the paper-holding device a double space upon maintained depression of each key.

4. A type-writing machine having a plurality of type-keys each having a stroke of unvarying length, a paper-holding device, means for feeding said device, and an component controlled by each key for causing said device to be fed a single or a double space at the will of the operator.

5. A type-writing machine having a plurality of type-keys each having a stroke of unvarying length, and means whereby a line of words made up of single-spaced letters, said words separated by blank spaces, may be printed by the actuation of the type-keys without recourse to an independent spacing key or bar.

6. A type-writing machine having a plurality of type-keys each having a stroke of unvarying length, a paper-holding device, means for feeding said device and an component controlled by each of the type-keys

for permitting the feeding of said device, said component having a stop movable automatically into and out of operative position to vary the length of the feeding movement of said device.

7. A type-writing machine having a plurality of type-keys each having a stroke of unvarying length, a paper-holding device, means for feeding said device, and an component having a stop for permitting said device to be fed one space, and having a stop controlled by each key for permitting said device to be fed a double space.

8. A type-writing machine having an attachment consisting of mechanism for permitting the carriage to be fed a double space, or a single space automatically, upon the maintained depression of each single key.

9. An attachment for a type-writing machine comprising a movable stop adapted to be secured to the pawl-carrier of said machine to limit the movement of the pawl, and means automatically operated upon the depression of each key for moving said stop out of and into operative relation to said pawl.

10. An attachment for a type-writing machine comprising a non-yielding pawl, a yielding pawl, a pawl-carrier, a movable stop adapted to be moved to the pawl-carrier to limit the movement of the yielding pawl, means for moving said stop in one direction, and means for moving it and returning its movement in the other direction.

11. A type-writing machine having a carriage-feeding component controlled by each type-key, said component being provided with a movable stop adapted to permit the carriage to move a single space or a double space and an automatic timing regulator for said stop.

12. A type-writing machine having a carriage-feeding component controlled by each type-key, and having alternately-operable stops for varying the feeding movement of the carriage, whereby said carriage may be fed automatically a single space or a double space on the depression of each key.

13. A type-writing machine having a carriage-feeding component, said component including a double-space stop, and a single-space stop adapted to be moved upon each depression of each key into and out of operative position, and a series of keys, each of which operates said spacing-component.

14. A type-writing machine having a carriage-feeding component, a stop thrown into one position by the actuation of each type-key to limit the movement of the carriage to a single space, and means for returning said stop to another position, to permit the carriage to move a double space.

15. A type-writing machine having a series of letter or type keys, a paper-holding device, and means controlled by the duration of depression of each key for imparting a differential movement to the paper-holding device.

16. The combination with an component for a type-writing machine, of a movable stop for varying the operation of said component, said movable stop being operable a predetermined period of time at each actuation of the component, whereby the carriage may be fed automatically a single space or a double space according to the duration of depression of the key.

17. The combination with an component including a carrier actuated by any of the type-keys and having a stationary pawl and a movable pawl, of a movable stop thrown into one position with relation to the movable pawl at each actuation of a type-key, and means for automatically returning the stop to another position, whereby the carriage may be fed automatically a single space or a double space according to the duration of depression of the key.

18. An attachment for a type-writing machine having a movable stop to limit the movement of a portion of the component, means for moving said stop to operative position and timed means for returning said stop to inoperative position, whereby the carriage may be fed automatically a single space or a double space according to the duration of depression of the key.

19. In a type-writer, a letter-key in combination with a reactionary device for causing a variable movement of the paper-carriage, said reactionary device being operated by said letter-key and being adjustable as to the duration of its action, whereby the carriage may be fed automatically a single space or a double space according to the duration of depression of the key.

20. In a type-writer, the combination with the paper-carriage and component mechanism, of a reactionary device operable by the depression of any one of a plurality of letter-keys, whereby said keys, when depressed, for an abnormal period of time, cause a movement of the paper-carriage of abnormal length.

21. A type-writing machine having a plurality of type-keys, each having a stroke of unvarying length, and an component provided with a single yielding pawl adapted to engage a toothed bar and stops operable upon the depression of each of the type-keys at any time for permitting the pawl to yield a single space or a double space, and thereby permit the feeding of the carriage a single space or a double space.

700,609. ELECTRICALLY-PROPELLED VEHICLE FOR SINGLE-RAIL ELEVATED RAILWAYS. FRED S. REER, Trichinopoly, England. Filed Feb. 24, 1902. Serial No. 95,408. (No model.)

Claim.—An electrically-propelled vehicle for a single-rail elevated railway, comprising a body for accommodation of passengers, pivoted and mounted on spring-actuated angle-rollers on bogies, which carry in the middle driving-wheels and at the sides electric motors connected by chain gear to the driving-wheels which also carry at the side spring-actuated lateral guide-wheels and conducting-wheels pressed by springs on a conducting-rail mounted on insulators, substantially as described.

700,610. TEMPER-SCREW. GEORGE F. REA, Shreveville, W. Va. Filed June 27, 1901. Serial No. 64,260. (No model.)

Claim.—In a device of the class described, the combination of a temper-screw having a threaded upper portion and provided with an extended lower portion forming a smooth shank, the latter being provided at its lower end with a head, the cross-head slidably mounted on the smooth shank of the temper-screw and capable of movement longitudinally thereof, vertical links located at opposite sides of the shank and supported by the cross-head, and a combining-spring located between the links and arranged on the smooth shank and interposed between the head thereof and the said cross-head and yieldingly supporting the latter, substantially as and for the purpose described.

700,611. STOVEPIPE-THIMBLER. BRUCE DILLINGER, South Whitley, Ind. Filed Jan. 14, 1902. Serial No. 68,069. (No model.)

Claim.—1. A stovepipe-thimble, composed of the circular plate or disk, the pipe-section or sleeve passing therethrough and having its ends

split, the adjusting-plate carried by said ends, the ring or band surrounding the projecting end of the thimble, the adjusting device for said band, and the cap or cover secured over and upon the adjusting device and having a portion engaging the adjusting-bolt to secure the cover in place.

2. A stovepipe-thimble, consisting of the split pipe-section or sleeve, the adjusting-plate engaging the split portions of the sleeve, the band surrounding the split sleeve and having an adjusting-bolt engaging its free ends, and a cover having a flange engaging the bolt to secure the cover over the adjusting device.

700,612. KIPPER. ARTHUR W. BARNETT, Owen, Ind., assignor of one-third to H. H. Bond, Louisville, Ky. Filed Jan. 7, 1902. Serial No. 64,110. (No model.)

Claim.—1. In a hinge the combination of two pivoted leaves having knuckles provided with shoulders located to interlock when the hinge is open, a curved notched tongue carried by one of said leaves which is constructed to engage an aperture in the other of said leaves when said shoulders interlock, substantially as described.

2. In a hinge the combination of two pivoted leaves, one of said leaves having a curved tongue provided with a square notch, the other of said leaves having an aperture therein located to be engaged by said tongue when the hinge is closed, said leaves having shoulders thereon which are constructed to interlock and permit the said square notch in said tongue to drop and engage the lower side of said aperture, substantially as described.

700,613. HARNES-MOTION FOR LOOMS. THOMAS BRYAN and MERRILL O. BRYAN, Portland, R. I., assignors to Bryn-More Company, Portland, Me., a Corporation of Maine. Filed July 13, 1901. Serial No. 62,796. (No model.)

Claim.—1. A harness-motion for looms, comprising a heddle-frame, a cam-actuated jack, and rack and segment mechanism interposed between said jack and said frame for positively actuating the latter.

2. A harness-motion for looms, comprising a heddle-frame, one or more depending racks attached to said frame, guides for said frame, one or more toothed segments engaging said rack or racks, a pivoted jack or lever attached to said segment or segments, and a cam for actuating said jack.

3. A harness-motion for looms, comprising a heddle-frame, means engaging the ends of said frame for guiding it vertically, and cam-actuated mechanism connected to said frame for moving it positively first in one direction and then in the other, all of the connections between the cam and the frame being rigid or inflexible.

4. A harness-motion for looms comprising a heddle-frame, guides for said frame, one or more bell-cranks connected to said frame, a cam-actuated jack connected to said bell-crank or bell-cranks to reciprocate said frame.

5. A harness-motion for looms, comprising a heddle-frame, means for guiding said frame, a pivoted jack, means connecting said jack with said heddle-frame, and a cam having a star-shaped cam-groove for actuating said jack, all of the connections between the cam and the frame being rigid or inflexible.

6. A harness-motion for looms comprising a heddle-frame, a cam having a cam-groove, a pivoted jack having a projection entering said groove, one or more bell-cranks located below the said heddle-frame and connected thereto, and a connecting-rod connecting said jack with said bell-crank or bell-cranks, substantially as described.

7. A harness-motion for looms comprising a heddle-frame, a rack connected to said heddle-frame, a guide for said rack, a toothed segment engaging said rack and holding it in the said guide, and means for actuating said segment.

700,614. PIN SETTING OR RESETTING DEVICE FOR BOWL-ING-ALLEYS. EDWARD D. BURN, Cleveland, Ohio. Filed Nov. 1, 1901. Serial No. 64,786. (No model.)

Claim.—1. In a pin setting and resetting device the combination of an alley, a platform arranged at the rear end of said alley, vertical guides arranged at the sides of said platform, a plate mounted so as to slide freely between said guides, openings formed in said plate and corresponding to the position of the pins on said platform, means for normally holding said plate suspended above said platform and means for causing said plate to approach said platform, substantially as described and for the purpose set forth.

2. In a pin setting and resetting device the combination of a platform, pins arranged upon and normally supported by said platform, pulleys mounted above said platform, ropes secured to said pins and supported by said pulleys, counterbalancing-weights secured to the free ends of said ropes above the level of the said platform, locking devices for holding the ropes against the pull of the weights, means for releasing said locking devices when the pins become displaced from their normal positions, vertical guides arranged at the sides of said platform, a plate arranged to slide vertically in said guides, means for normally holding said plate at an elevation above said platform and means for causing said plate to approach said platform, substantially as described and for the purpose set forth.

3. In a pin setting and resetting device, the combination of a platform, pins arranged upon and normally supported by said platform, pulleys mounted above said platform, ropes secured to said pins and supported by said pulleys, counterbalancing-weights secured to the free ends of said ropes above the level of the platform, buttons secured on said ropes, a plate arranged above said ropes, and provided with projections adapted to engage said buttons, a trigger arranged below said plate, and means for causing the said trigger to release the buttons from said plate, substantially as described and for the purpose set forth.

4. In a pin setting and resetting device the combination of a plat-

form, pins arranged upon and normally supported by said platform, pulleys mounted above said platform, ropes secured to said pins and supported by said pulleys, counterbalancing-weights secured to the free ends of said ropes above the level of the platform, buttons secured on said ropes, a plate arranged above said ropes and provided with projections adapted to engage said buttons, a trigger arranged below said plate, and means for causing the said trigger to release the buttons from said plate, a stop for limiting the travel of said buttons when released from said projections and means for replacing said buttons in engagement with said plate, substantially as described and for the purpose set forth.

5. In a pin setting and resetting device the combination of a platform, pins arranged upon and normally supported by said platform, pulleys mounted above said platform, ropes secured to said pins and supported by pulleys, counterbalancing-weights secured to the free ends of said ropes above the level of the platform, buttons secured on said ropes, a plate arranged above the said ropes and provided with projections adapted to engage said buttons, a trigger arranged below said plate, blocks strung upon said ropes and operatively connected with said trigger, and buttons secured on said ropes above said blocks and arranged to engage said blocks when the said pins are moved from their normal positions, substantially as described and for the purpose set forth.

6. In a pin setting and resetting device, the combination of a platform, pins arranged upon and normally supported by said platform, pulleys mounted above said platform, ropes secured to said pins and supported by said pulleys, counterbalancing-weights secured to the free ends of said ropes above the level of the said platform, locking devices for holding the ropes against the pull of the weights, means for releasing said locking devices when the pins become displaced from their normal positions, indices secured to said weights and arranged to indicate the positions of the respective pins, a frame located at the front end of said alley constituting a guideway for the said weights, a movable bottom arranged in said frame to support said weights when in their lowest positions and means for lifting said bottom so as to restore the said weights to their normal positions, substantially as described and for the purpose set forth.

7. In a pin setting and resetting device the combination of a platform, pins arranged upon and normally supported by said platform, pulleys mounted above said platform, ropes secured to said pins and supported by said pulleys, counterbalancing-weights secured to the free ends of said ropes above the level of said platform, a frame located at the front end of said alley constituting guideways for said weights, a movable bottom arranged in said frame to support said weights when in their lowest positions, buttons secured on said ropes, a plate arranged above said ropes, and provided with projections adapted to engage said buttons, a trigger arranged below said plate, blocks strung upon said ropes and operatively connected with said trigger, buttons secured on said ropes, above said blocks and arranged to engage said blocks when the pins are in their normal positions, vertical guides arranged at the sides of the platform, a plate arranged to slide vertically in said guides and form a stop to limit the upward movement of the said pins, means for holding said plate at an elevation above said platform, means for causing said plate to approach said platform, means for causing the first-mentioned button to come into engagement with the said first-mentioned plate and means for lifting the said weights to their normal positions, all arranged substantially as described and for the purpose set forth.

700,615. RAILWAY-SWITCH. EDWIN R. CANNELL, Watling ton, B. C. Filed Jan. 2, 1902. Serial No. 64,911. (No model.)

Claim.—1. In an automatic device for operating railway-switches, the combination of a pair of fulcrumed contact-levers, a slotted fulcrumed lever-plate positioned lengthwise the railway and connected to the switch-frags, and a chain of levers connecting the contact-levers with said plate.

2. In a device for operating railway-switches, the combination with the fulcrumed chain of levers, of the pivoted lever-plate having a diagonal slot and operated by one of the levers of said chain, and the arms connecting the lever-plate with the switch-frags.

3. In a device for operating railway-switches, the combination with the pivoted slotted lever-plate, links connecting the plate with the switch-frags, and the fulcrumed lever having a stud or pin working in the slot of the said plate, of the fulcrumed contact-levers, and the levers connecting the contact-levers with the pin-lever.

4. The combination, with the switch-frags, the levers, and the links, of a pivoted lever-plate connected to the frags by said links, and having a slot in which one of the fulcrumed levers is operated to move the plate and work the frags.

5. In a device for operating railway-switches, the combination of the contact-levers at right angles to the railway, a pivoted lever-plate lengthwise the railway and connected to the switch-frags, the links connecting to the contact-levers, and the lever pivotedly connecting the links together and fulcrumed so as to give the free end of the lengthwise lever a transverse movement.

6. In an automatic device for operating railway-switches, the combination of the contact-levers at right angles to the railway, a diagonally-slotted plate lengthwise the railway and connected to said levers, and connections from the switch-frogs to the said plate so that the movement of the latter will work the frogs.

7. The combination with the contact slotted levers, and the links one of which is pivoted to one of said levers at one side of its fulcrum-point, and the other of which is pivoted to the other of said levers at the other side of its fulcrum-point, of a lever crosswise the railway and operated by the said links, and a diagonally-slotted plate lengthwise the railway and operated by the cross-lever to work the switch-frogs.

700,618. PROCESS OF CONVERTING CELLULOSE INTO FERMENTABLE SUGAR. ALEXANDER CLAMER, Aachen, Germany. Filed Mar. 23, 1901. Serial No. 82,414. (No specimens.)

Claim.—1. The process for converting cellulose into fermentable sugar which consists in subjecting the moist material to the action of sulfuric anhydride vapors and then suitably boiling the mass thus obtained with water.

2. The process for converting cellulose into fermentable sugar which consists in suitably heating the moist material, subjecting the material to the action of sulfuric anhydride vapors, and then suitably boiling the mass thus obtained with water.

3. The process for manufacturing fermentable sugar which consists in subjecting moist sawdust to the action of sulfuric anhydride vapors, and then suitably heating and boiling the mass thus obtained with water.

4. The herein-described process for manufacturing fermentable sugar, which consists in suitably heating moist sawdust, subjecting the material to the action of sulfuric anhydride and then boiling the mass in an open vessel with water.

700,617. KNIFE. STEPHEN R. CHAMBER, Middletown, Pa. Filed Jan. 12, 1902. Serial No. 82,403. (No model.)

Claim.—1. A knife having a blade with a sharpened edge extending the full length thereof and terminating in a point from which a convex blunt edge extends upwardly and rearwardly, a forwardly-projecting sharpened spur intersecting with the rear terminal of the said convex blunt edge, a concave serrated back portion, a serrated recess in the back portion, and a handle adjacent to the forward extremity of which the said serrated recess is located.

2. As an improved article of manufacture, a knife-blade having a sharpened edge and a concave back which is serrated its full length and has a serrated recess near the rear terminal thereof.

700,618. GRATE. CHARLES T. COE, New York, N. Y. Filed Aug. 2, 1901. Serial No. 71,284. (No model.)

Claim.—1. In a grate, the combination with a supporting-frame, of rocking frames mounted in said supporting-frame, and each consisting of supporting-bars, division-plates, and a strengthening-web connecting said division-plates, leaves or sections mounted on said rocking frame and between said division-plates, and means for rocking said frames, substantially as described.

2. In a grate, the combination with a supporting-frame, of rocking frames mounted in said supporting-frame and each consisting of supporting-bars, division-plates, and a strengthening web or plate connecting said division-plates, and leaves or sections mounted in said rocking frames and between said division-plates, said leaves having their edges resting upon the supporting-bars of said rocking frame and provided with lugs or projections fitting in recesses formed in said division-plates, substantially as described.

3. In a grate, the combination with a rocking frame, said frame consisting of longitudinal parallel supporting-bars, division-plates cast integral with said bars, and provided with recesses, and a strengthening plate or web connecting the lower edges of said division-plates, the end plates

of said rocking frame being provided with concave legs or projections forming bearings for said frame, of leaves or sections, adapted to fit in said frame and on said supporting-bars, and provided with legs or projections on their ends to fit in said recesses in said division-plates, substantially as described.

700,619. ELEVATOR SIGNAL DEVICE. SAMUEL R. COLLIER, New York, N. Y., assignor to Elevator Supply & Repair Company, a Corporation of Illinois. Filed Feb. 10, 1902. Serial No. 98,308. (No model.)

Claim.—1. In a building having a plurality of floors in combination a plurality of elevator-cars passing said floors, a relatively independent circuit to each car, a signal on each car controlled by the circuit to that car, and means located at the "starting-floor" and controlling said independent circuits, whereby the signal on any car may be operated from said floor and independently of the signals on the other cars.

2. In a building having a plurality of floors in combination, a plurality of elevator-cars passing said floors, a relatively independent and normally open circuit to each car, a signal on each car controlled by the circuit to that car and operative on the closing of its circuit, and means located at the "starting-floor" and controlling said independent circuits, whereby the signal on any car may be operated from said floor and independently of the signals on the other cars.

3. In a building having a plurality of floors in combination, a plurality of elevator-cars passing said floors, a relatively independent and normally open circuit to each car, a signal on each car controlled by the circuit to that car and operative on the closing of its circuit, and a switch in each circuit located at the "starting-floor" for closing said independent circuits, whereby the signal on any car may be operated from said floor and independently of the signals on the other cars.

4. In a building having a plurality of floors in combination, a plurality of elevator-cars passing said floors, a relatively independent and normally open circuit to each car, a signal on each car controlled by the circuit to that car and operative on the closing of its circuit, said signal being "made" only so long as its circuit is closed, and a switch in each circuit located at the "starting-floor" for closing said independent circuits, whereby the signal on any car may be operated from said floor and independently of the signals on the other cars.

5. In a building having a plurality of floors in combination, a plurality of elevator-cars passing said floors, a relatively independent circuit to each car, an audible signal on each car controlled by the circuit to that car, and means located at the "starting-floor" and controlling said independent circuits, whereby the signal on any car may be operated from said floor and independently of the signals on the other cars.

6. In a building having a plurality of floors in combination, a plurality of elevator-cars passing said floors, a source of electromotive force, a relatively independent circuit to each car in parallel from said source of electromotive force, a signal on each car controlled by the circuit to that car, and means located at the "starting-floor" and controlling said independent circuits, whereby the signal on any car may be operated from said floor and independently of the signals on the other cars.

7. In a building having a plurality of floors in combination, a plurality of elevator-cars passing said floors, a relatively independent circuit to each car, a signal on each car controlled by the circuit to that car, and means located at the "starting-floor" and controlling said independent circuits, whereby the signal on any car may be operated from said floor wherever said cars may be in their travel and independently of the signals on the other cars.

8. In a building having a plurality of floors in combination, a plurality of elevator-cars passing said floors, a relatively independent circuit to each car, a signal on each car controlled by the circuit to that car, and means located at the "starting-floor" and controlling said independent circuits, whereby the signal on any car may be operated from said floor and independently of the signals on the other cars, and signal devices also at the "starting-floor" automatically indicating the location of the different cars in their travel.

9. In a building having a plurality of floors in combination, a plurality of elevator-cars passing said floors, each of said cars being provided with a signal to indicate an intending passenger, means located at different floors to cause said signals to be operated, a relatively independent and normally open circuit to each car, a second signal on each car controlled by the circuit to that car and operative on the closing of its circuit, said latter signal being "made" only so long as its circuit is closed, and means located at the "starting-floor" and controlling said independent circuits, whereby a signal may be transmitted from said floor to any of said cars independently of the other cars.

10. In a building having a plurality of floors in combination, a plurality of elevator-cars passing said floors, each of said cars being provided with a signal to indicate an intending passenger, means located at different floors to cause said signals to be operated, a relatively independent and normally open circuit to each car, a second signal on each car controlled by the circuit to that car and operative on the closing of its circuit, said latter signal being "made" only so long as its circuit is closed, and means located at the "starting-floor" and controlling said independent circuits, whereby a signal may be transmitted from said floor to any of said cars independently of the other cars, and signal devices also located at the "starting-floor" and visible to the starter, for visibly indicating at all times the location of each car.

700,620. WEIGHING-MACHINE. EDGAR H. COOK, Brooklyn, N. Y. Filed June 6, 1901. Serial No. 63,308. (No model.)

Claim.—1. In a weighing-machine, the combination with the weighing mechanism and an indicator-dial, of a pneumatic retarding device connected to the case of the weighing-machine, and a rocking bar pivoted to the case connected at one end to the pneumatic device and at the other

end to the vertical rod of the weighing-machine for controlling the oscillatory movement of the dial, substantially as set forth.

2. In a weighing-machine, the combination with the weighing mechanism, a face covering the indicator-dial thereof and having an opening therein and a shutter for normally covering the opening, of a pneumatic device for controlling the oscillatory movement of the weighing mechanism and indicator-dial, a hand-operated mechanism for effecting the movement of the shutter, and devices actuated by the movement of the shutter and acting in connection with the movement of the indicator-dial when the shutter is moved to discover the weight, substantially as and for the purposes set forth.

3. In a weighing-machine, the combination with the indicator-dial, the springs and other parts of the weighing mechanism and the vertical rod extending therefrom to the platform of the weighing-machine, of a plunger-rod connected to the case of the weighing-machine and placed vertically therein, a pivot-post 40 also upon said case, a rocking bar 38 mounted upon said pivot-post and having a longitudinal mortise at one end, a pin 39 passing through the mortise of said bar into the vertical bar of the weighing-machine to connect the parts, a piston in the plunger-rod, and a rod 37 connected thereto and pivotally connected to the rocking bar, substantially as and for the purposes set forth.

4. In a weighing-machine, the combination with the weighing mechanism, a face covering the indicator-dial thereof and having an opening therein, and a shutter for normally covering the opening, and a hand-operative mechanism for actuating the shutter, of a device for engaging the shutter and holding the same away from the opening in the face, and a yielding device connected to the axis of the indicator-dial and adapted to be engaged by the abutment shutter-holding means, substantially as set forth.

5. In a weighing-machine, the combination with the weighing mechanism, a face covering the indicator-dial thereof and having an opening therein, a shutter for normally covering the opening, a pivotal shutter-arm for the shutter, and a hand-operative mechanism for swinging the shutter-arm and shutter, of a toothed wheel mounted upon the axis of the indicator-dial, means for limiting the movement of the same and for providing a yielding movement thereof in opposite directions with reference to said axis, and means substantially as described operated by the shutter-arm for simultaneously engaging the said toothed wheel and holding the shutter away from the opening in the face, substantially as set forth.

6. In a weighing-machine, the combination with the weighing mechanism, a face covering the indicator-dial thereof and having an opening therein, a shutter for normally covering the opening, a pivotal shutter-arm for the shutter, and a hand-operative mechanism for swinging the shutter-arm and shutter, of a toothed wheel loosely mounted upon the axis of the indicator-dial, means for connecting said toothed wheel to said axis and for providing a limited movement of the toothed wheel in relation thereto, means for yieldingly connecting the said toothed wheel to

the said axis and which means provides for the movement of the said toothed wheel in relation to the said axis in either direction a distance agreeing with the limiting movement of the abutment means, and means substantially as described operated by the shutter-arm for simultaneously engaging the said toothed wheel and holding the shutter away from the opening in the face, substantially as set forth.

7. In a weighing-machine, the combination with the weighing mechanism, a face covering the indicator-dial thereof and having an opening therein, a shutter for normally covering the opening, a pivotal shutter-arm for the shutter, and a hand-operative mechanism for swinging the shutter-arm and shutter, of a hub of stepped form in cross-section secured to the axis of the indicator-dial, a toothed wheel loose upon the said stepped hub and having oppositely-placed mortises, and screws passing through the mortises into the said hub for securing the toothed wheel to the hub, and yet providing for a predetermined movement in opposite directions proportioned to the length of the said mortises, a pin upon the said toothed wheel, and pins at opposite points in the periphery of the said hub, and helical springs connected at one end to the pin of the toothed wheel and at their other ends to the pins of the said hub, whereby the toothed wheel is free to turn in either direction in extent equal to the length of the said mortises, putting one of the said springs under tension and by which the toothed wheel is returned to its normal position, the said springs acting together to maintain the toothed wheel in a predetermined relation to the said axis of the indicator-dial, and means substantially as described operated by the shutter-arm for simultaneously engaging the said toothed wheel and holding the shutter away from the opening in the face, substantially as set forth.

8. In a weighing-machine, the combination with the weighing mechanism, a face covering the indicator-dial thereof and having an opening therein, a shutter for normally covering the opening, a pivotal shutter-arm for the shutter, and a hand-operative mechanism for swinging the shutter-arm and shutter, of a toothed wheel mounted upon the axis of the indicator-dial, means for limiting the movement of the same and for providing a yielding movement thereof in opposite directions with reference to said axis, a pivotal arm, a latch-rod on the arm of the shutter engaging a slot in said pivotal arm, a rocker-bar pivoted to the said arm, and means for maintaining the relation of the pivotal arm to the rocker-bar, a device connected to the rocker-bar adapted to engage the toothed wheel and a device forming a continuation of the rocker-bar and adapted to engage the latch-rod of the shutter-arm whereby the shutter-arm is held by the latch-bar and is released therefrom, substantially as set forth.

9. In a weighing-machine, the combination with the weighing mechanism, a face covering the indicator-dial thereof and having an opening therein, a shutter for normally covering the opening, a pivotal shutter-arm for the shutter, and a hand-operative mechanism for swinging the shutter-arm and shutter, of a toothed wheel mounted upon the axis of the indicator-dial, means for limiting the movement of the same and for providing a yielding movement thereof in opposite directions with reference to said axis, a pivotal arm 1 carried by an upright of the case and mortised at one end, a latch-rod connected to the shutter-arm and at one side of the said arm passing into the said mortise, a rocker-bar pivotally connected to the said arm, a tooth 27 carried by said rocker-bar and adapted to engage the teeth of the toothed wheel, a latch-bar pivoted to one end of the rocker-bar, and a spring for actuating the same, a latch-rod upon the free end of the latch-bar adapted to engage the latch-rod of the shutter-arm, and spring-acting devices connecting the pivotal arm and the rocker-bar and also the latch-bar in relation to one another, substantially as set forth.

10. In a weighing-machine, the combination with the weighing mechanism, a face covering the indicator-dial thereof and having an opening therein, a shutter for normally covering the opening, a pivotal shutter-arm for the shutter, and a hand-operative mechanism for swinging the shutter-arm and shutter, of a toothed wheel mounted upon the axis of the indicator-dial, means for limiting the movement of the same and for providing a yielding movement thereof in opposite directions with reference to said axis, an arm 1 connected by a screw-rod pivotally to an upright 2 of the case, said arm 1 being provided at one end with a mortise 25 having a portion of circular form and a portion with parallel edges, a latch-rod 31 on the shutter-bar 3 projecting from one side of said shutter-bar into said mortise, auxiliary arm 1' extending in opposite directions from the opposite end of the said arm 1, a rocker-bar 4 and a screw-rod 34 for pivotally connecting the same to the arm 1, said bar 4 having a mortised portion 26 encircling the screw-rod 34, and an adjustable removable tooth 27 connected to the rocker-bar 4 above the screw-rod 34, a spring-actuated latch-bar 5 pivoted at one end of the rocker-bar 4, a latch-rod 28 on the free end of said latch-bar adapted to engage the latch-rod 31 of the shutter-arm, a screw-rod 35 extending through the opposite end of the rocker-bar 4, and springs 33, 34 connected at one end to the said screw-rod 35 and at the other ends to studs in prolongations of the auxiliary arm 1', substantially as and for the purposes set forth.

700,621. METAL WINDOW. ARTHUR W. COOPER, Chicago, Ill.
Filed Feb. 2, 1902. Serial No. 55,122. (No model.)

Claim.—1. A hollow or tubular sheet-metal window-frame member embracing a trough-shaped inner part and an outer part or wall, said inner and outer parts being joined at their edges by the bending of the margins of one part over the margins of the other part, so as to form flanges which extend outwardly from the side faces of the frame.

2. A hollow or tubular sheet-metal window-frame member embracing a trough-shaped inner part having outwardly-bent margins, and an outer part or wall, the side edges of which are bent around and interlocked with the said outwardly-bent margins of the inner part so as to form flanges which extend outwardly from the side faces of the frame.

3. A hollow or tubular sheet-metal window-frame member embracing a trough-shaped inner part having outwardly-bent margins, and an outer part or wall the side margins of which are bent around the outwardly-bent side margins of the inner part, said outer part or wall being bent near its side margins to provide shoulders which are parallel with and fit against the inner faces of the side walls of the trough-shaped member.

4. A tubular sheet-metal cash-frame bar consisting of an inner trough-shaped member, and an outer trough-shaped member the side walls of which are parallel with and adapted to fit between the side walls of the inner member; the margins of the inner and outer members being bent outwardly and folded together so as to form laterally-projecting flanges in the outer margin of the bar.

5. A tubular sheet-metal cash-frame bar consisting of an inner trough-shaped part, the margins of which are bent outwardly, and an outer trough-shaped member the side walls of which are parallel with and fit between the side walls of the inner member, the said side walls of the outer member being bent outwardly and folded around the outwardly-bent margins of the inner member to secure said members together.

6. The combination with a window-frame, of a sheet-metal cash, consisting of an inner trough-shaped part and an outer trough-shaped part, the side walls of which are parallel with and fit within the side walls of the inner part; the margins of said inner and outer parts being bent outwardly and joined by folding the margin of one part over the margin of the other part so as to form outwardly-projecting flanges on the cash, and steps on the frame, consisting of metal strips, the inner margins of which are separated by a space from the frame so as to constitute a groove to receive the flanges on the cash.

7. The combination with a tubular sheet-metal cash provided with a marginal recess or groove, the side walls of which are formed by the outer parts of the side walls of the cash-frame, of a weather-strip secured against

one of the side walls of the groove and having a flexible edge which projects beyond the edge of the cash.

8. The combination with a tubular sheet-metal cash consisting of two trough-shaped members fitted one within the other and forming a marginal groove, of a weather-strip secured to the side walls of said groove and having a flexible edge which projects beyond the margin of the cash.

9. The combination with a tubular sheet-metal cash, consisting of two trough-shaped parts, fitted one within the other with their side walls in contact and secured together by the folding or interlocking of their side margins, of a weather-strip secured to the side wall of said groove, and having a flexible edge which projects beyond the margin of the cash.

10. The combination with a tubular sheet-metal cash provided with a marginal recess or groove, of a weather-strip consisting of a folded strip of flexible material, and a folded metal strip embracing the edges of the flexible strip, said weather-strip being secured to one of the side walls of the groove with the fold of the flexible strip projecting beyond the margin of the cash.

11. The combination with a tubular sheet-metal cash consisting of two trough-shaped parts inserted one within the other with their side walls in contact with each other, and forming a marginal groove in the cash, and two weather-strips secured one to each side wall of the said groove and provided with flexible edges which project beyond the margin of the cash.

12. The combination with a frame having flat inner faces and cash-steps thereon, of a cash having a tubular sheet-metal frame provided with a marginal groove, the side walls of which are formed by the outer parts of the side walls of the tubular cash-frame, and a weather-strip secured to one of the side walls of the groove and having a flexible edge adapted for contact with the inner face of the frame when the cash is in place therein.

13. The combination with a frame and a pivoted cash, of holding means for holding the cash in its open position, comprising a toothed bar and a detent adapted to engage the said bar, said holding means including parts which are held in operative relation by solder or fusible metal and which, upon the solder becoming fused by heat, become disconnected and release the cash.

14. The combination with a pivoted cash, of holding means for holding the cash in its open position, embracing a toothed segment attached to the cash concentrically with the pivotal axis thereof and a spring-pressed detent; said holding means embracing parts which are held in operative relation by solder or fusible metal.

15. The combination with a pivoted cash, of a notched segment on the cash and a spring-pressed detent adapted to engage the said segment; the said detent consisting of two parts which are joined by solder or fusible metal.

16. The combination, with a pivoted cash, of a notched segment, the teeth of which are secured thereto by solder or fusible metal, and a spring-pressed detent consisting of two parts joined by solder or fusible metal.

17. The combination, with a pivoted cash, of a holding device embracing a toothed segment which is rigidly attached to the cash and is located in a plane outside of the margin of said cash, and a detent adapted to engage the said segment, said holding device embracing parts which are held in operative relation by solder or fusible metal.

18. The combination with a tubular sheet-metal frame, of a cash pivoted to the frame and a holding device for the frame embracing a toothed segment attached to one end to the cash and located in a plane outside of the margin of the cash, said frame being provided with an aperture through which the segment enters the same, and a spring-pressed detent on the frame adapted to engage said notched segment, said holding means embracing parts which are held in operative relation by solder or fusible metal.

19. The combination with a cash, of means for pivotally supporting the same, embracing a bracket attached to the cash and a pivot-rod attached to said bracket, and means for holding the cash in its open position, embracing a toothed segment attached to the said bracket concentrically with the said pivot-rod, and a spring-pressed detent adapted for engagement with the said segment.

20. The combination with a cash, of means for pivotally supporting the cash and holding it open, embracing a bracket, a pivot-rod attached thereto, a toothed segment and a segment-supporting arm; said bracket, segment and supporting-arm being formed of a single casting.

21. The combination with a pivoted cash, of a toothed holding-segment, a spring-pressed detent having the form of a bolt, one end of which is adapted to engage the segment and a casing in which the detent slides, the end portion of the bolt which engages the teeth of the segment being attached to the body part thereof by a soldered joint.

22. The combination with a pivoted cash, of a toothed holding-segment, the teeth of which are made separated from each other and are separately attached to the segment by solder, and a spring-pressed detent

adapted to engage the said segment; the end portion of said segment which engages the teeth of the segment being attached to the body part thereof by solder.

25. The combination with a sheet-metal ash-tray, provided with a marginal groove, of a bracket and a pivot-rod attached to said bracket; said bracket being provided with an integral attaching-plate which is secured within the groove in the ash-tray by attachment to one of the side walls of the said groove.

26. The combination with a tubular sheet-metal ash-tray, consisting of two trough-shaped parts, fitted one within the other with their side walls in contact and forming a marginal groove in said ash-tray, of a pivot-rod and a bracket for connecting the pivot-rod with the ash-tray, said bracket having an integral attaching-plate which is secured to the ash-tray within said groove by attachment to the side walls of the said trough-shaped parts; said side walls being notched for the passage of the bracket.

27. The combination with a metal ash-tray, of a hollow sheet-metal mullion, and connectors adapted to enter the ends of the mullion and having stems which enter and are secured to the ash-tray.

28. The combination with a hollow sheet-metal ash-tray, provided with grooves to receive the ends of the glass, of a sheet-metal mullion and connectors adapted to engage the ends of the mullion and having flat-sided stems adapted to fit within the grooves in the ash-tray.

29. The combination with a hollow sheet-metal ash-tray consisting of inner and outer trough-shaped parts, one of which fits within the other, said frame having U-shaped parts which form glass-receiving grooves, of a sheet-metal mullion, and connectors adapted to engage the ends of the mullion and provided with flat-sided stems adapted to fit within the glass-receiving grooves, and screws inserted through the outer trough-shaped parts of the frame and engaging said stems.

30. The combination with a metal ash-tray, of a hollow sheet-metal mullion having flattened central and lateral parts, and connectors having the shape adapted to enter the ends of the mullion, and stems which enter and are secured to the ash-tray.

31. The combination with a hollow or tubular sheet-metal ash-tray, the upper cross-bar of the frame having a U-shaped part to receive the ends of the glass which extends outwardly into contact with the outer wall of said cross-bar, and the lower cross-bar of the frame having a U-shaped part which is separated by a space from the outer wall of the cross-bar, a sheet-metal mullion, a connector for the upper end of the mullion having a flat side or stem which abuts against the inner wall of the U-shaped part of the ash cross-bar and is secured to the said cross-bar by a screw passing through the outer wall of said cross-bar and through said U-shaped part and a connector for the lower end of the mullion provided with a flat-sided stem which passes through an aperture in said U-shaped part and abuts at its end against the outer wall of the said lower cross-bar and is secured to the said cross-bar by a screw which passes through the said outer wall thereof.

32. A pivoted, tubular sheet-metal ash-tray, consisting of inner and outer trough-shaped members inserted one within the other and joined at their edges; the lower cross-bar of the ash-tray being provided with an outwardly and downwardly extending flange formed by extension of the marginal parts of both members, which are joined by folding at the outer edge of said flange.

33. The combination with a window-frame, of a sheet-metal ash consisting of inner and outer parts the side margins of which are bent outwardly and folded together to form marginal flanges at both sides of the ash, and steps extending around the frame at the inner and outer faces of the ash, said steps consisting of metal strips secured to the ash at their outer margins and separated by a space at their inner margins from the frame so as to form grooves to receive the outwardly and inwardly extending flanges in the ash, the steps at the inner side of the ash being detachably secured to the frame.

34. The combination with a window-frame, of a sheet-metal ash consisting of inner and outer parts, the side margins of which are bent outwardly and folded together to form marginal flanges at both sides of the ash, and steps extending around the outer face of the ash, said steps consisting of metal strips secured to the frame at their outer edges and separated by a space from the frame at their inner edges so as to form a groove to receive the flange on the ash; the step at the bottom or sill member of the frame having its inner edge adapted to bear against the outer face of the lower cross-bar of the ash to prevent the entrance of water between the ash and sill.

35. The combination with a sheet-metal window-frame, and a ash having an outwardly-extending marginal flange, of steps or the frame consisting of metal strips bent into U form and secured to the frame with their edges directed toward the ash.

36. The combination with a tubular sheet-metal frame, of a ash-tray, and means for securing said tray to the frame consisting of one soldered to the inner face of the frame, and screw-bolts inserted through

the stop and engaging the said nuts, said screw-bolts having heads which bear against the outer faces of the stop.

700,629. CLUTCH-OPERATING MECHANISM. HARRY E. GUNN, Brooklyn, N. Y. Filed Dec. 2, 1900. Serial No. 34,008. (No model.)

Claim.—1. In a clutch mechanism the combination with a shaft and fixed and movable clutch members mounted thereon, of an abutment-collar fixed to the shaft, a loose collar between the abutment-collar and the movable clutch member, a screw supported by said loose collar, a nut upon the screw, means for causing the relative rotation of nut and screw, and a thrust-bearing between nut and movable clutch member.

2. In a clutch mechanism the combination with a shaft and fixed and movable clutch members on the shaft, of an abutment fixed to the shaft, a clutch-operating screw outside of and non-rotatable with the shaft, a nut for said screw, means for causing relative rotation of nut and screw, and thrust-bearings transmitting the thrust of said screw and nut respectively to the abutment and movable clutch member.

3. In a clutch mechanism the combination with a shaft and fixed and movable clutch members mounted thereon, of an abutment-collar fixed to the shaft, a loose collar between the abutment-collar and the movable clutch member, a screw supported against rotation by said loose collar, a nut upon the screw, means for turning said nut and a thrust-bearing between nut and movable clutch member.

4. In a clutch mechanism the combination with a shaft, a fixed and a movable clutch member carried by said shaft, and an abutment-collar secured to the shaft, of a non-rotating collar on the shaft between the abutment-collar and the movable clutch member, screws and nuts carried by said non-rotating collar and thrust-bearings transmitting the pressure of said screws and nuts respectively to the abutment-collar and to the movable clutch member, said means for causing relative rotation of screws and nuts.

5. In a clutch mechanism the combination with a shaft, and fixed and movable clutch members on the shaft, of an abutment-collar secured to the shaft, a non-rotatable collar about the shaft between the abutment-collar and the movable clutch member, screws supported against rotation by said non-rotating collar, nuts upon the screws, thrust-bearings transmitting the pressure of said nuts and screws respectively to the movable clutch member and the abutment-collar, and means adjustably secured to said nuts to turn them.

6. In a hoisting-engine, the combination with a power-driven shaft, a drum loosely mounted thereon, a clutch member fixed to the shaft, and means for frictionally engaging said clutch member with the drum to drive it, of an exterior abutment upon the shaft, nuts and screws exterior of and having a fixed position relative to the shaft, and substantially parallel with the shaft, means for causing relative rotation of nuts and screws, said nuts and screws having thrust-bearings respectively upon the drum and shaft-abutment.

7. In a clutch mechanism the combination with a shaft, and fixed and movable clutch members on the shaft, of an abutment-collar secured to the shaft, a loose collar about the shaft between the abutment-collar and the movable clutch member, said loose collar having a pin engaging the shaft-support or other fixed member to prevent turning of the collar, threaded pins or screws supported against turning by said loose collar, nuts on said screws, operating-levers adjustably coupled to said nuts to turn them, and thrust-bearings interposed respectively between the loose collar and abutment and between the nuts and removable clutch member.

8. In a hoisting-engine the combination with a power-driven shaft, a drum loosely thereon, and a friction driving connection between shaft and drum operated by movement of the drum lengthwise the shaft, of an abutment-collar secured to the shaft, a collar loosely surrounding the shaft between the abutment-collar and the drum, a pin connecting said loose collar and the shaft-support to prevent rotation of the collar, screws carried

by the abutment-collar and extending lengthwise the shaft, nuts on said screws, thrust-bearings respectively between the loose abutment-collar and between the nuts and drum, and levers clamped upon the nuts whereby they may be turned to operate the friction mechanism.

9. In a hoisting-engine the combination with a power-driven shaft, a drum loosely thereon, and a friction driving connection between shaft and drum operated by movement of the drum lengthwise the shaft, of an abutment-collar secured to the shaft, two loose and non-rotating collars upon the shaft between the drum and the abutment-collar, threaded pins carried by one of said loose collars and freely passing through the other, nuts upon said pins engaging said other loose collar, thrust-bearings between said collars and the abutment-collar and drum respectively, and levers secured to said nuts to turn them, and to thereby separate the loose collars.

10. In a clutch mechanism the combination with a shaft, of fixed and movable clutch members mounted on said shaft, a support or abutment rotating with said shaft and adjacent said movable clutch member, a non-rotating collar on said shaft between said movable clutch member and said support or abutment, said collar being split or separable to permit its removal from said shaft, and to thereby allow movement of the movable clutch member on said shaft and separation of said clutch members, and a screw-nut outside of the shaft periphery and adapted when given relative rotation to exert pressure between said abutment and the movable clutch member to operate the clutch, and means for rotating said screw.

700,628. EYEGLASS. AUGUSTUS R. COTTER, San Antonio, Tex. Filed Oct. 21, 1901. Serial No. 79,467. (No model.)

Claim.—1. The eyeglass herein described provided with the spring-bow, with the ear-bow to bear under the frontal bone, the nosepieces provided with eyes, the spring-plates adjustably supported at one end and free at their other ends and provided near their free ends with slots for the eyes on the nosepieces and the nosepieces being provided with portions clamping the springs all substantially as described whereby the nosepieces will be given a tension toward each other by the spring-plates and will slide along the said spring-plates substantially as set forth.

2. The combination with the opposite glasses and the longitudinally-movable nosepieces, of spring-plates adjustably supported at one end and free at their other ends and provided near their free ends with slots for the eyes on the nosepieces and the nosepieces being provided with portions clamping the springs all substantially as described whereby the nosepieces will be given a tension toward each other by the spring-plates and will slide along the said spring-plates substantially as set forth.

3. In eyeglasses the combination with the opposite glasses, of the nosepieces, the spring-plates for actuating the nosepieces and along which the nosepieces are slidable longitudinally, and spring-carriers for the outer ends of the nosepieces substantially as set forth.

4. In eyeglasses the combination of the spring-plates, the nosepieces held to and slidable along the spring-plates, and spring-connections between the nosepieces and their respective glasses substantially as set forth.

5. Eyeglasses provided with nosepieces which are movably longitudinally or in the direction of their lengths, and with springs independent of the bow-spring for actuating such nosepieces substantially as set forth.

6. An eyeglass provided with ear-bow devices to bear under the frontal bone and also provided with spring-actuated nosepieces arranged to yield longitudinally and toward and from each other and with devices along which the nosepieces are movably substantially as set forth.

7. The combination of lenses, nosepieces arranged between said lenses and movable longitudinally, springs independent of the bow-spring for actuating the nosepieces and connections between the nosepieces and their respective lenses, substantially as set forth.

8. The combination with the lenses, of the springs extending between said lenses and yielding laterally toward and from the same, and nosepieces movable longitudinally along the said springs and arranged to be actuated thereby, and connections between the glasses and the nosepieces whereby the springs actuate the nosepieces longitudinally and laterally substantially as set forth.

700,624. SELF-ADJUSTING MACHINE. CLARENCE F. GUNN, North Abington, Mass., assignor to Standard Shoe Machinery Company, East Orange, N. J., a Corporation of New Jersey. Filed Feb. 14, 1900. Serial No. 61,800. (No model.)

Claim.—1. In a sole-trimming machine, the combination with a trimming-knife, of a movable guide-support co-operating with the work, a guide arranged to move upon said support, an eccentric journaled in the guide-support arranged to control the movement of the guide, and means for operating the eccentric.

by and bodily movable with the guide-support for adjusting the guide at substantially right angles to the plane of movement of the trimming-knife.

2. In a sole-trimming machine, the combination with a trimming-knife, of a movable guide-support co-operating with the work, a guide arranged to move upon said support, an eccentric journaled in the guide-support arranged to control the movement of the guide, and means for operating the eccentric.

3. In a sole-trimming machine, the combination with a trimming-knife, of a movable guide-support co-operating with the work, a guide arranged to move upon said support, an eccentric journaled in the guide-support arranged to control the movement of the guide, means for operating the eccentric, and means for limiting the movement of said eccentric, both of which means are carried by the guide-support.

4. In a sole-trimming machine, the combination with a trimming-knife, of a movable guide-support co-operating with the work, a reciprocating guide mounted upon said support, means carried by the guide-support and bodily movable therewith for moving said guide to vary the distance between its end and the trimming-knife, and stops also carried by the guide-support for limiting the movement of the guide in either direction.

5. In a sole-trimming machine, the combination with a trimming-knife, of a movable guide-support co-operating with the work, a reciprocating guide mounted upon said support, means carried by the guide-support and bodily movable therewith for moving the guide to vary the distance between its end and the trimming-knife, and adjustable stops also carried by the guide-support for limiting the movement of the guide in either direction whereby the width of the sole outside the upper may be varied.

6. In a sole-trimming machine, the combination with a trimming-knife, of a movable support co-operating with the work and provided with guide-supporting grooves, a guide mounted in said grooves and adapted to be moved to vary the distance between its working end and the trimming-knife, and a cam journaled in the support and coacting with the guide to control the movement thereof.

7. In a sole-trimming machine, the combination with a trimming-knife, of a movable support co-operating with the work and provided with guide-supporting grooves, a guide mounted in said grooves and adapted to be moved to vary the distance between its working end and the trimming-knife, a cam journaled in the support and coacting with the guide to control the movement thereof, an arm operable to move the cam, and adjustable stops for limiting the movement of the cam, said arm and stops being carried by the guide-support.

8. In a sole-trimming machine the combination of a trimming-knife, a guide-support, a guide arranged to be moved endwise in said support, an eccentric cam journaled in the guide-support arranged to control the movement of said guide, and vary the relative positions of its working end and the trimming-knife during the trimming operation, and means under the control of the operator for moving said cam, and limiting-stops for regulating the extent of movement of said guide.

9. In a sole-trimming machine the combination of a trimming-knife, a pivoted feeding-lever, a reciprocating gage mounted in the working end of said feeding-lever, a cam for moving said guide endwise to vary the distance between its working end and the trimming-knife, an arm for controlling the movement of the cam, said cam and arm being carried by the feeding-lever, a segmental plate secured to said feeding-lever and provided with a series of pin-bolts, and stop-pins adapted to be interchangeably mounted in said holes to vary the movement of said cam.

10. In a sole-trimming machine the combination of a trimming-knife, a guide-support, a guide arranged to be moved endwise in said support, and means wholly carried by and bodily movable with the guide-support under the control of the operator whereby the relative position of said guide and trimming-knife may be varied during the trimming operation.

11. The combination with a trimming-knife, of a feeding-lever, an independently-movable guide mounted upon the lever, and means carried by the lever for actuating the guide.

12. The combination with a trimming-knife, of a feeding-lever, an independently-movable guide mounted upon the lever, and an eccentric carried by the lever for actuating the guide.

13. The combination with a trimming-knife, of a feeding-lever, a guide movable upon the lever, a shaft journaled in said lever, and an eccentric mounted upon the shaft and coacting with the guide.

14. The combination with a trimming-knife, of a feeding-lever, a guide movable upon the lever, a shaft journaled in said lever, an eccentric mounted upon the shaft and coacting with the guide, and a lever carried by the shaft.

15. The combination with a trimming-knife, of a feeding-lever, a guide movable upon the lever, a shaft journaled in said lever, an eccentric mounted upon the shaft and coacting with the guide, a lever carried by the shaft, and means for limiting the movement of the lever.

16. The combination with a trimming-knife, of a feeding-lever, a guide movable upon the lever, a shaft journaled in said lever, an eccentric mounted upon the shaft and coacting with the guide, a lever carried by the shaft, and adjustable means for limiting the movement of the lever.

17. The combination with a trimming-knife, of a feeding-lever, a guide movable upon the lever, a shaft journaled in said lever, an eccentric mounted upon the shaft and coacting with the guide, and a lever carried by the shaft.

18. The combination with a trimming-knife, of a lever divided at its end to form arms, a guide movably mounted upon the arms, and an eccentric journaled between the arms and coacting with the guide.

19. The combination with a trimming-knife, of a lever, a guide movably mounted upon the lever and provided with an L-shaped slot, and an eccentric having its periphery entering and substantially conformed to the slot.

20. The combination with a knife, of a lever divided at its end to form arms, a guide movably mounted upon the arms, an eccentric journaled between the arms and coacting with the guide, and means for rotating the eccentric carried by the lever.

700,695. AUTOMATIC CAR-COUPLING. JOHN BARKER, Batherglan, Scotland. Filed Jan. 10, 1901. Serial No. 42,708. (No model.)

Claim.—1. In a car-coupler, the combination with the jaws having pin-openings formed through the walls thereof, and a pin enter tension adapted to enter said openings, of a springing member connected to the coupler, and a counterbalanced pin-holder pivoted to said member and normally depending between the jaws to close the openings in the walls thereof and to prevent the pin from moving to coupled position.

2. In a car-coupler, the combination with jaws having pin-openings formed therein, and a coupling-pin under tension adapted to enter said openings, of a cross-bar for operating the pin, a sleeve or collar having a limited movement on the cross-bar, and a counterbalanced pin-holder pivoted to the sleeve or collar and normally depending between the jaws to close the openings in the walls thereof, and to prevent the pin moving to coupled position.

3. In a car-coupler, the combination of the jaws having pin-openings therein and a cross-bar, of a coupling-pin under tension adapted to enter said openings, a cross-bar connected to the coupling-pin, a link pivoted between the jaws, a pin-link carried by the said link, and a pawl carried by the cross-bar to operate the pin-link and engaging within the recess of the jaws to lock the pin in its withdrawn position.

4. In a car-coupler, the combination with the jaws having pin-openings formed in the walls thereof, of a coupling-pin under tension entered in one of said openings, a counterbalanced pin-holder pivoted over and depending between said jaws to prevent the pin passing through the said openings into coupled position, the cross-bar G, the sleeve or collar loosely mounted on said cross-bar, said counterbalanced pin-holder being carried by said sleeve or collar, a bracket connecting the cross-bar and coupling-pin, a recess A' at the inner end of one of the jaws and a projecting lip or flange A' formed at the inner end of the other jaw, the pawl P pivoted to said cross-bar adapted to fall behind the lip or flange A' on the inner end of the jaws, thereby locking the coupling-pin in the coupled position.

700,696. FINE-WATER-FILTER AND KEATER. JAMES DAVIS, Chicago, Scotland. Filed Sept. 17, 1901. Serial No. 78,717. (No model.)

Claim.—1. A fine-water-filtering apparatus, comprising a casing having an opening at one end, a filtering device adapted to be inserted into said casing, a cover adapted to close said casing, a screw passing through said cover, an inlet-chamber, a sediment-collector, a blow-off, an outlet-chamber, valve-chests T, T' and X, double-faced valves P and R, a single valve S arranged in said chests and suitably supported wheels and spindles in operative connection with said valves, substantially as shown and described.

2. A fine-water-filtering apparatus, comprising a casing having an opening at one end, a filtering device adapted to be inserted into said casing, a cover adapted to close said casing, a screw passing through said cover, an inlet-chamber, a sediment-collector, a blow-off, an outlet-chamber, valve-chests T, T' and X, double-faced valves P and R, a single valve S arranged in said chests and suitably supported wheels and spindles in operative connection with said valves, said filtering device being composed of inlet-gratings R, outlet-gratings O and filter-discs D arranged in series and forming inlet to the water to be filtered, and outlet to the filtered water, substantially as shown and described.

3. In an apparatus of the class described a filter-casing, a filtering device adapted to be placed therein; valve-chests T, T' and X in said casing, double-faced valves P and R and a single-faced valve S arranged in said chests, means for operating said valves, an inlet in communication with one of said valve-chests, a heater in communication with said inlet, and an outlet also in communication with one of said valve-chests, whereby water may be heated, or filtered, or both, or neither, as desired, substantially as shown and described.

700,697. SUB-CARRIER. KARE BERNHARD, Pilsen, Austria-Hungary, assignor to Pilsen of Maschinenbau, Aktiengesellschaft in Pilsen, Pilsen, Austria-Hungary. Filed Dec. 26, 1901. Serial No. 57,587. (No model.)

Claim.—1. In a gun-carriage, the combination with the trail and its shoe, of a spade pivotedly connected in the shoe and provided with suitable projecting means, and means pivotedly mounted in the shoe and engaging the projecting means of the spade for retaining the latter in its operative position.

2. In a gun-carriage, the combination with the trail thereof and its shoe, of a spade pivotedly connected to the shoe and provided with suitable projecting means, means pivotedly connected with the shoe and engaging the projecting means of the spade for retaining the latter in its operative position, and means carried by the trail to limit the movement, in one direction, of the spade.

3. In a gun-carriage, the combination with the trail thereof and its shoe, of a spade pivotedly connected to the shoe and provided with suitable projecting means, a bolt secured to the shoe, a sleeve mounted upon said bolt and provided with means adapted to engage the projecting means of the spade for retaining the latter in its operative position, and means for operating the said sleeve.

able projecting means, a bolt secured to the shoe, a sleeve mounted upon said bolt and provided with means adapted to engage the projecting means of the spade for retaining the latter in its operative position, and means for operating the said sleeve.

4. In a gun-carriage, the combination with the trail thereof and its shoe, of a spade pivotedly connected with the shoe and provided with suitable projecting means, a bolt secured to the shoe, a sleeve mounted upon said bolt and provided with means adapted to engage the projecting means of the spade for retaining the latter in its operative position, means for operating the said sleeve, and means carried by the trail for limiting the movement, in one direction, of the spade.

5. In a gun-carriage, the combination with the trail thereof and its shoe, of a spade pivotedly connected with the shoe and provided with suitable projecting means, a bolt secured to the shoe, a sleeve mounted upon said bolt and provided with means adapted to engage the projecting means of the spade for retaining the latter in its operative position, and a handle secured to the said sleeve for operating it.

6. In a gun-carriage, the combination with the trail thereof and its shoe, of a spade pivotedly connected with the shoe and provided with suitable projecting means, a bolt secured to the shoe, a sleeve mounted upon said bolt and provided with means adapted to engage the projecting means of the spade for retaining the latter in its operative position, means extending through the said sleeve for operating it, said trail provided with a wheel adapted to receive one end of the means extending through the sleeve.

700,698. MINING-MACHINE. HENRY A. DUNN, Columbus, Ohio, assignor to Joseph A. Jeffrey, Columbus, Ohio. Filed Oct. 14, 1901. Renewed Oct. 22, 1901. Serial No. 29,490. (No model.)

Claim.—The combination with the bed, the carriage, resting upon and sliding along the bed and the horizontally-extending chain having cutters mounted upon and advanced by the carriage, of the rotating holder mounted at the front of the carriage, and adapted to engage with the horizontal wall of the end-belt, and a support for said rotary holder adapted to be adjusted in position vertically, substantially as set forth.

700,699. DRAFT ATTACHMENT FOR RAILROAD-CARS. HERMAN J. BERNHARD, Vicksburg, Miss., assignor of said title to Leon Hahn, Vicksburg, Miss. Filed Dec. 26, 1901. Serial No. 58,688. (No model.)

Claim.—1. A draft attachment for railroad-cars, comprising a draft-coupling for attachment to the end and side sills of the car-body, a depending carry-iron on one end of the said draft-coupling, a depending apertured bracket on the other end of the draft-coupling, a draw-bar resting on the said carry-iron and having an apertured lug, draft-rods extending through the said bracket and lug, and springs held between the said bracket and lug, the draft-rods extending through the springs, and the latter being seated on seats formed on the opposing faces of the bracket and lug, as set forth.

2. A draft attachment for railroad-cars, comprising a draft-coupling

for attachment to the end and side sills of the car-body, a depending carry-iron on one end of the said draft-coupling, a depending apertured bracket on the other end of the draft-coupling, a draw-bar resting on the said carry-iron and having an apertured lug, draft-rods extending through the said bracket and lug, springs held between the said bracket and lug, the draft-rods extending through the springs, and the latter being seated on seats formed on the opposing faces of the bracket and lug, and lugs held on the outer ends of the draft-rods to abut against the outer end of the lug on the draw-bar, as set forth.

3. A draft attachment for railroad-cars, comprising a draft-coupling arranged for attachment to the car-sills, depending arms on the forward end of the draft-coupling, a carry-iron supported between the arms, a depending bracket on the rear end of the draft-coupling and formed with longitudinal apertures and spring-cuts, a draw-bar supported on the carry-iron and having its shank provided with a lug having apertures and spring-cuts in alignment with the apertures and spring-cuts on the draft-coupling bracket, springs extending between the said bracket and the said lug and seated on the seats thereof, draft-rods extending through the said registering apertures, spring-cuts and springs, and lugs held on the ends of the draft-rods and adapted to abut against the forward end of the lug, as set forth.

4. A draft attachment for railroad-cars provided with a draft-coupling, comprising a base-plate fitting against the under side of the end sill and the side sill, a flange extending upward on the forward end of the base-plate for attachment to the front face of the end sill, depending arms on the front end of the base-plate for supporting a carry-iron, a bracket depending from the rear end of the base-plate and having longitudinal apertures and spring-cuts, and a cross-piece having side flanges and rising longitudinally from the base-plate at the rear end thereof for attachment to the side sills of the car-body, as set forth.

5. A draft attachment for railroad-cars, comprising a base-plate fitting against the under side of the end sill and the side sill and provided at its forward end with an upwardly-projecting flange for attachment to the front face of the end sill and with a depending apertured bracket having slots in its front face, and with an upwardly-extending cross-piece connected with the base-plate by side flanges, a draw-bar working between the arms and resting on the carry-iron, the rear end of the draw-bar having an apertured lug having slots around the apertures, draft-rods extending through the apertures of the bracket and lug and having surrounding the rods with their ends in the slots of the said bracket and lug, as set forth.

6. In a draft attachment for railroad-cars, a draft-coupling secured to the end and side sills of a car and provided at its front end with an upwardly-projecting flange and depending arms having a roller mounted between them and at its rear end with a depending apertured bracket, a draw-bar having its shank working in the guideway and provided with an apertured lug at its rear end, draft-rods extending through the apertures of the bracket and lug and provided at their ends with steps for engaging

aid leg, and springs surrounding the rods between said leg and bracket, as set forth.

700,680. ACCOUNT-BOOK. **HERMAN L. DUNHAM**, Fayetteville, Ark. Filed July 10, 1901. Serial No. 67,771. (No model.)

Claim.—1. In an account-book, a section-plate formed of trough-shaped sections secured laterally together, in combination with a series of movable sections placed in said trough-shaped sections, and strips forming leaves carried by said movable sections, substantially as and for the purposes described.

2. The combination with a section-plate having a series of flanged, hollow, sections secured laterally together, of movable sections placed in said hollow sections, strips provided with springs and placed in said movable sections, strips forming leaves carried by said movable sections, and fixed pins adapted to removably retain said spring-strips and said leaves in place.

3. The combination with a section-plate, formed of hollow parallel sections, secured laterally together and provided with flanges *d*, of a series of movable sections, strips *e*, provided with springs, leaves having columns marked on them, carried by said movable sections, and sliding covers adapted to be moved on said parallel sections, substantially as shown.

4. The combination with a section-plate comprising a series of trough-shaped devices, secured laterally together, of a series of name-plates, each of which is hinged at one edge to a flange of said section-plate, the opposite edge of the name-plate being removably secured by means of a removable pin passed through holes in projections on said section-plate, substantially as and for the purposes described.

700,681. MODIFIED MILK AND PROCESS OF OBTAINING SAME. **Hans von Bornemann**, Frankfurt-on-the-Main, Germany, assignor to the Fortworte, vorm. Heister, Lueden & Brining, Höchst-on-the-Main, Germany, a Corporation of Germany. Filed Dec. 4, 1900. Serial No. 53,993. (No specimens.)

Claim.—1. The herein-described process of treating cow's or goat's milk to render it more digestible by infants and invalids, which consists in adding a rennet ferment to the milk, whereby the same is separated into whey and a curd coagulate, and then mechanically breaking up said coagulate into fine flakes so that only fine flakes remain in suspension in the whey, substantially as set forth.

2. As a new product, cow's or goat's milk, containing whey, and a curd coagulate in fine flakes held in suspension in said whey, said milk resembling the original milk in composition, taste and appearance, substantially as set forth.

700,682. LEAD-PENCIL. **DAVID DUNHAM** and **VERNEY J. COOPER**, London, England. Filed Feb. 5, 1908. Serial No. 98,000. (No model.)

Claim.—A lead-pencil consisting of a tubular pencil part to carry a usual loose lead, a closed tapered part on point end of pencil, a point-cap to fit on same and to compress the closed part to place the lead, a series of transverse holes in pencil part, a peg to insert in each hole to prevent the loose lead from being pushed in by writing, all substantially as hereinbefore described.

700,688. MEANS FOR SECURING CENTER PIVOTS TO AXLES IN GUNS. **GUNTER BERGMANN**, Mannheim, Germany. Filed Jan. 5, 1908. Serial No. 98,914. (No model.)

Claim.—1. Means for securing the center pivot of guns consisting of a ring formed of separable segments seated in a space formed by grooves in the center pivot and pivot-bearing, substantially as described.

2. Means for securing the center pivot of guns consisting of a center pivot provided with a peripheral groove, a pivot-bearing having a groove opposite the peripheral groove, and a ring formed of separable segments seated in the space formed by said grooves, substantially as described.

3. In a pivot-bearing for guns, a pivot having a peripheral groove, a pivot-bearing having a groove opposite said peripheral groove and an arched in the pivot-bearing for admitting segments into the space formed by said grooves, for forming a segmental ring therein, substantially as described.

4. A pivot-bearing for guns comprising a pivot provided with a peripheral groove, a pivot-bearing provided with a groove opposite said peripheral groove, an opening in the pivot-bearing to admit segments to be inserted into the space formed by said grooves to form a segmental ring, said segments being provided with internally-curve-threaded openings to facilitate their removal, and a screw-threaded plug for closing the opening in the pivot-bearing, substantially as described.

700,684. INCANDESCENT VAPOR-BURNER. **BRADDOCK L. FOX**, Warren, Ind. Filed June 16, 1901. Serial No. 63,114. (No model.)

Claim.—1. A vapor-burner, comprising a mixing-chamber, a burner having communication therewith, a gas and air mixing tube extending from the lower portion of the said chamber and curved upward and inward toward the burner with its open end adjacent to said burner, a platform extending from the mixing-chamber, an oil-supply pipe, a valve-casing below the platform and into which the supply-pipe leads, a valve in said casing, and an oil-tube leading upward from the valve-casing through the platform along one side of the burner and thence down the other side and having its end bent outward and supported from the platform opposite the open end of the mixing-tube, said oil-tube being provided with a coil at the upper portion over the burner for converting the oil into gas when heated, as set forth.

2. A vapor-burner, comprising a gas and air mixing chamber, a curved mixing-tube extending from said chamber and having its open upper end terminating adjacent to the burner, as set forth or platform co-

located outward from the burner, a tubular supporting device extended upward from said arm or platform, a supply-pipe for oil extending through said supporting device, a valve-casing with which said supply-pipe communicates, a tube extended upward from said valve-casing and having a generating-coil at its upper portion above the burner, the opposite open end of said tube being opposite the opening in said mixing-tube, and a valve for controlling the passage of oil to the said generating-tube, substantially as specified.

3. A vapor-burner, comprising a globe-carrying post, a mixing-chamber carried by the post, and communicating with the burner, a mixing-tube extending from the bottom of the mixing-chamber and curved upward and inward toward the burner with its open end adjacent to the said burner, a lateral arm extending from the mixing-chamber, a tubular support for the burner, said support extending upward from the arm, an oil-pipe extending through the said support, a valve-casing connected to the mixing-chamber and with which the oil-pipe communicates, a valve in said casing, and a generating-tube extending from the valve-casing up along one side of the burner and thence down the other side, and having its open end opposite the mixing-tube, said generating-tube being provided with a coil above the burner, as set forth.

700,685. WAGON-BODY. **JOHN W. FROST**, Lakeland, Minn. Filed Nov. 12, 1901. Serial No. 51,951. (No model.)

Claim.—1. In a wagon-body, the combination with the bottom sides and ends, the sides and ends each having a detachable connection with each other, and a cross-bar secured to the bottom at about the center thereof with its ends projecting beyond the sides and provided at its ends with a projection on its upper face, of a triangular brace finally secured to each side and provided at its base with an inwardly-extending projection, the base of the brace resting loosely on the projecting ends of the cross-bar with their projections extending under the bottom into sockets or U-shaped

keepers, the said braces being restrained from lateral movement by the projections of the bar, substantially as shown and described.

2. In a wagon-body, the combination with the bottom sides and ends, the sides and ends each having a detachable connection with each other, a pair of spaced cross-bars secured to the bottom at about the center thereof and projecting beyond the sides and a bar connecting the ends of the cross-bars, of a pair of triangular braces secured to each side and each provided at its base with an inwardly-extending projection, the base of the brace resting loosely on the projecting ends of the cross-bar inside of the bar connecting said cross-bars and having their projections extending under the bottom into sockets or U-shaped keepers substantially as shown and described.

3. In a wagon-body the combination with the bottom, of sides and ends, the sides and ends each being constructed of iron and provided with a plurality of spaced and aligned eyes formed by bending integral extensions thereof into loop shape as shown, which loops interlock with each other when the parts are assembled, of independent U-shaped securing-braces, each comprising vertical members entering the interlocked eyes of the sides and ends locking them together, and a horizontal member of a length equal to the distance apart of the sides of the body whereby the said sides will be locked against lateral movement when the securing-brace is in position, all substantially as shown and described.

4. In a wagon-body the combination with the bottom, of sides and ends having detachable connection with each other, and a cross-bar secured to the bottom at about the center thereof with its ends projecting beyond the sides and provided at its ends with a projection on its upper face, of a triangular brace finally secured to each side and provided at its base with an inwardly-extending projection, the base of the brace resting loosely on the projecting ends of the cross-bar with their projections extending under the bottom into sockets or U-shaped keepers, the said braces being restrained from lateral movement by the projections of the bar, and lock devices at either side of the braces supported in keepers on the sides and adapted to engage or enter sockets on the bottom substantially as described.

700,686. KINDERGARTEN LOOM. **FRANCIS A. PORTER**, New York, N.Y. Filed Feb. 6, 1908. Serial No. 98,708. (No model.)

Claim.—1. A loom having end bars provided with bars and the bars on one of the bars extending entirely through the same and the bar that has the bars extending entirely through the same also having a longitudinal groove, rods the ends of which are fitted in said bars, and a stop for said rods fitted in said groove.

2. A loom having end bars provided with bars and one of the bars extending entirely through the same and the bar that has the bars extending entirely through the same also having a longitudinal groove, the ends of which are fitted in said bars, a stop for said rods slidable in said groove, and guiding means for said stop.

3. A loom having end bars provided with bars and the bars on one of the bars extending entirely through the same and the bar that has the bars extending entirely through the same also having a longitudinal groove, the ends of which are fitted in said bars, a stop for said rods slidable in said groove and staples clamping said stop.

4. A loom having end bars provided with bars and rods fitted in the bars, the bars being of greater number in the respective bars than

the rods and extending transversely of the base and the horns of one of the horns extending entirely through the same, and said bar that has the horns extending entirely across the same having a longitudinal groove, and a step for said rods in said groove.

5. A beam having end bars provided with horns and the horns on one of the horns extending entirely through the same and the bar that has the horns extending entirely through the same also having a longitudinal groove, the ends of which are fitted in said horns, a step for said rods fitted in said groove, and headed studs carried by the end bars, for receiving the washers.

700,687. INITIAL FINGER-RING. FREDERICK S. PEY, JR., St. Louis, Mo. Filed Mar. 15, 1902. Serial No. 96,394. (No model.)

Claim.—1. The combination with a finger-ring provided with apertures, of an initial and hinged arms carried by said initial adapted for introduction through said apertures to interlock with each other beneath the band of the ring, substantially as described.

2. The combination with a finger-ring, provided with apertures, of an initial, arms hinged to said initial adapted for introduction through said apertures, one of said arms being provided with an orifice and a stud carried by the other arm adapted to enter said orifice to hold said arms in interlocked position when folded together within the ring, substantially as described.

3. The combination with a finger-ring having a counterbore and a stud carried by said counterbore, of an initial and hinged arms carried by said initial, one of said arms being provided with an orifice and a stud carried by the other of said arms adapted for introduction into said orifice when the arms are in folded condition within the band of the ring, substantially as described.

700,688. EXTENSIBLE WINDOW-SCREEN. WILLIAM J. GREENHART, Cortland, N. Y. Filed Feb. 25, 1900. Serial No. 703,771. (No model.)

Claim.—An article of manufacture, an extensible window-screen consisting of two sections slidably connected together, one upon the other, said sections having grooves in the inner adjacent faces of the side rails, registering with each other, rollers loosely arranged in said grooves, and steps for retaining the rollers in the grooves.

700,689. REVERSIBLE DEVICE FOR ENGINE. ROBERT E. HARRIS and HENRY P. WALLER, Twin Valley, Minn. Filed Aug. 31, 1901. Serial No. 73,582. (No model.)

Claim.—The combination with a shaft or rotary member having the legs 8, 9 and the sliding collar 15, of the eccentric 10 having the

11 in which said legs 8, 9 are mounted, the reversibly-tapered cam 20 movable with said sliding collar and acting on said eccentric to adjust the same to and from concentricity with its axis of rotation, and an eccentric-rod driven by said eccentric, substantially as described.

700,640. BURNISHING-DAKE SHARPENER. GEORGE W. HALL, ST. LOUIS, Mo. Filed Sept. 20, 1901. Serial No. 78,708. (No model.)

Claim.—1. In a device for the purpose set forth, the combination of the operative handle, the arms pivoted thereto, the pivotal links connecting said arms, one of said arms having a jaw at its forward end, a movable knife coated in said jaw, the other of said arms having a projecting table extending into the path of said knife and having means for securing a burr thereon.

2. In a device for the purpose set forth, the combination of the operative handle pivoted together and having projections extending beyond the point of pivot, operative arms pivoted to the projections of the handles, links connecting said arms and pivoted at their opposite ends thereto, a jaw in the outer end of one of said arms, a knife mounted in said jaw and adjustably secured therein, a table projecting from the other of said arms in the path of said knife, and a set-screw in said table adapted to engage and confine the end of the burr.

700,641. COMBINED STUMP-PULLER AND TREE-TRANSPLANTER. WILLIAM A. HARRIS, Bardwell, Ky., assignor, by direct and mesne assignments, of two-thirds to Francis Martin Haganscamp, Bardwell, Ky. Filed July 11, 1901. Serial No. 67,572. (No model.)

Claim.—1. An apparatus of the character described, comprising opposite side, upright guides rising from the side, a lifting-beam movable between the guides, inclined corner-braces between the side and the respective upright guides, a substantially horizontal tongue-frame connected to the upright guides and the front inclined braces, a tongue carried by the frame, and a wheel connected to the front end of the side.

2. An apparatus of the character described, comprising opposite side, frames rising therefrom, lifting means mounted upon the frame, and front and rear corner braces adjustably connecting the opposite frames, the members of each pair of corner braces having a pivotal connection at their point of crossing, and also provided at their opposite ends with adjustable connections with the respective frames.

3. An apparatus of the character described, comprising opposite side, intermediate upright guides rising from the side, lifting means working between the guides, inclined braces between the tops of the guides and the opposite ends of the respective side, and front and rear corner braces adjustably connecting the respective side and upright guides, the members of each pair of corner braces having a pivotal connection at their point of crossing and the opposite ends of the members having connections with and adjustable longitudinally of the respective inclined braces.

4. In an apparatus of the character described, the combination of opposite side, intermediate upright guides rising therefrom, a lifting-beam working between the guides, lifting-jacks mounted upon the side and beneath the lifting-beam, pulleys carried by the upper ends of the guides, drums mounted upon and portions of the side, cables working over the respective drums and having their opposite ends connected to the adjacent ends of the lifting-beam and the corresponding drums, crank-handles for the drums, inclined braces extending from the tops of the guides to the opposite ends of the respective side, front and rear pairs of corner braces, the members of each pair of corner braces having a pivotal connection at their point of crossing, and the opposite ends of the members having adjustable connections with the respective inclined braces, a tongue-frame connected to the front inclined braces and the upright guides, a tongue carried by the frame, and a wheel connected to the front end of the side.

5. An apparatus of the character specified, comprising supporting-side, upright guides carried thereby, a lifting-beam movable between the guides, corner-braces connecting the side with the uprights, and adjustable cross-braces connecting the corner-braces.

6. An apparatus of the character specified, comprising supporting-side, upright guides carried thereby, a lifting-beam movable between the guides, corner-braces connecting the side and the uprights, adjustable cross-braces connecting the corner-braces, and a tongue connected with the uprights and the corner-braces.

7. A device of the character specified, comprising supporting-side, upright guides carried thereby, and a lifting-beam movable between the guides, said beam comprising a base-beam connected to the side and braces, struts interposed between the latter beams and the base-beam, a check-block bearing against the lower ends of the struts, and clamping means bearing against the bottom of the base-beam and the apex of the end beams.

8. A device of the character specified, comprising two supporting-side each composed of two members slidably spaced apart and closed at their lower ends by filling blocks, the chambers thus formed constituting receptacles for tools, cartridges, &c., upright guides having their lower ends secured between the side members, a lifting-beam movable between the guides, and means for operating the beam.

700,642. BURNISHING OR POLISHING MACHINE. ORIN A. HANCOCK, Wolcott, Minn., assignor to Charles A. Griskey and George Bernard, Boston, Mass. Filed Aug. 12, 1901. Serial No. 71,812. (No model.)

Claim.—1. A portable buffing or polishing apparatus, comprising an electric motor, a buffer carried and operated by said motor, and a handle pivotally attached to said motor whereby the buffer may be manually pressed against the material to be buffed or polished.

2. A portable buffing or polishing apparatus, consisting of an electric motor, oppositely-disposed handles attached to said motor whereby it may be easily manipulated, one of said handles being pivotally connected, and a chuck carrying a buffer and carried by the armature-shaft of said motor, substantially as described.

3. A portable buffing or polishing apparatus consisting of an electric motor having cross-bars attached to the pole-pieces at opposite sides of the armature of the motor, handles attached to said cross-bars, and a chuck carrying a buffer and carried by the armature-shaft of said motor, substantially as described.

700,643. TIME-POUNCE. ORIN A. HANCOCK, Boston, Mass., assignor to Fred. Krupp, Boston, Mass. Filed May 15, 1900. Serial No. 14,722. (No model.)

Claim.—1. In a time-pounce, the combination of a spindle and a powder-ring mounted to turn about said spindle, and said spindle having its rotational axis at the portion adjacent to the powder-ring reduced sufficiently

to insure lateral spreading of said reduced portion against the powder-ring by the inertia of the several parts on firing; whereby the powder-ring is jammed and prevented from turning, substantially as described.

2. In a time-fuse of the character specified, the combination of a spindle, a cap fitted to the outer end of the spindle and provided with a yielding bearing engaging the adjacent part of the fuse, and a powder-ring mounted to turn about said spindle, and said spindle having its rotational axis at the portion adjacent to the powder-ring reduced sufficiently to insure spreading of the spindle at said reduced portion by the inertia of the several parts on firing; whereby the powder-ring is jammed and prevented from turning, substantially as described.

3. In a time-fuse of the character specified, the combination of a spindle, a cap fitted to the outer end of the spindle and provided with a thin, circumferential vent or bearing engaging the outer end powder-ring, and an inner powder-ring adapted to turn about said spindle, and said spindle having its rotational axis at the portion adjacent to the inner powder-ring reduced sufficiently to insure spreading of the spindle at said reduced portion by the inertia of the several parts on firing; whereby the inner powder-ring is jammed and prevented from turning, substantially as described.

4. In a time-fuse, the combination of a spindle and a powder-ring mounted to turn about said spindle, and said spindle being hollowed out to reduce the rotational axis at the portion thereof in contact with the powder-ring sufficiently to insure lateral spreading of said reduced portion against the powder-ring by the inertia of the several parts on firing; whereby the powder-ring is jammed and prevented from turning, substantially as described.

700,644. FLUID-REGULATING DEVICE. JAMES HARRISON, Springfield, Vt. Filed Jan. 21, 1901. Serial No. 64,972. (No model.)

Claim.—1. A fluid regulating or measuring device comprising a two-part casing having a chamber formed between them, measuring means including a fluid-operated member located in one section of the casing, a valve independent of said member and located in said chamber, and means passing through the other section of said casing for operating said valve.

2. A fluid regulating or measuring device comprising a casing having a plurality of chambers with independent movable elements therein, inlet and outlet ducts leading from said chambers, and having their mouths arranged about a common center, and a centrally-located inlet-control, and an eccentric valve governing the passage of fluid through said ducts in succession.

3. A fluid regulating or measuring device comprising an expanding compartment having a resilient wall, means for permitting the ingress and egress of fluid into and out of said chamber, a continuously-rotatable valve operable independently of movement of the resilient wall, and an adjustable wall for said chamber having a boss for limiting the play of said resilient wall.

4. A fluid regulating or measuring device comprising an expanding compartment having a resilient wall, means for permitting the ingress and egress of fluid into and out of said compartment, a continuously-rotatable valve operable independently of movement of the resilient wall, a pin arranged to limit the play of said resilient wall, and an adjustable central pin adapted to engage the first-mentioned pin for adjusting it.

5. A fluid regulating or measuring device comprising an expanding compartment having a resilient wall, means for permitting the ingress and egress of fluid into and out of said chamber, a valve operable independently of the said resilient wall, a continuously-rotatable shaft on which the valve is eccentrically mounted, and a spring interposed between said valve and said shaft for holding said valve against its seat.

6. A fluid regulating or measuring device comprising a casing having two oppositely-disposed chambers each provided with a diaphragm which divides it into two expanding compartments, steps for limiting the movement of said diaphragms, and means for simultaneously adjusting said steps.

700,645. FLUID-REGULATING DEVICE. JAMES HARTNER, Springfield, Vt. Filed Jan. 21, 1901. Serial No. 64,974. (No model.)

Claim.—1. A fluid-regulating device comprising a cylinder having a loose differential piston, ducts leading to opposite ends of the cylinder to deliver fluid thereto, a pressure-chamber, an independent outlet, and a valve controlling the passage of fluid to said ducts, and permitting the escape of the fluid under augmented pressure to the said pressure-chamber, and of the fluid under lower pressure to said independent outlet.

2. A fluid-regulating device comprising a cylinder having a loose differential piston, a common inlet for both ends of the cylinder, independent outlets for the said cylinder ends, and a single valve for controlling the passage of fluid through said inlet and outlet.

3. A fluid-regulating device comprising a cylinder having a loose differential piston, a common inlet for both ends of the cylinder, a conduit for the fluid delivered under high pressure, a waste-conduit for the fluid delivered under low pressure, and a single valve for controlling the passage of fluid through said inlet and outlet.

4. A fluid-regulating device comprising a cylinder having a loose differential piston, suitable valve mechanism for supplying fluid to the opposite ends of said cylinder, separate ducts controlled by the valve mechanism, for conducting from the cylinder the low-pressure and the high-pressure fluid, and means consisting of a rigid adjustable stop for limiting the movement of said piston, and thereby varying the volume of the discharged fluid.

5. A fluid-regulating device comprising a casing having a plurality of cylinders with loose independent pistons therein, a single valve operable independently of movement of the pistons for permitting the ingress and egress of fluid into and out of said cylinders on both sides of the pistons, and provision for limiting the play of said pistons including members projecting through the cylinder ends, and a cap adjustably attached to said casing and having an inner face against which said members may abut.

6. A fluid-regulating device comprising a plurality of cylinders having loose differential pistons, a common accumulator-chamber for the high-pressure fluid, a common exhaust for the low-pressure fluid, and a common valve for said cylinders.

7. A fluid-regulating device comprising a plurality of cylinders having loose differential pistons, a common outlet for the high-pressure fluid, a common inlet for the low-pressure fluid, a common inlet to the cylinders to deliver fluid to both sides of the pistons, and an eccentric valve common to all of said cylinders.

8. A fluid-regulating device comprising a plurality of cylinders with differential pistons, a valve-seat having parts for the cylinders arranged in two concentric rows, an escape-port within the inner row of parts, an inlet-port between the said rows of parts, a common accumulator or discharge chamber, and an eccentric valve having two concentric chambers, substantially as described.

9. A fluid-regulating device comprising a plurality of cylinders with differential pistons, a valve-seat having parts for the cylinders arranged in two concentric rows, an escape-port within the inner row of parts, an inlet-port between the said rows of parts, a common accumulator or discharge chamber, and an eccentric valve having two concentric chambers, substantially as described.

700,646. FLUID-OPERATING DEVICE. JAMES HARTNER, Springfield, Vt. Filed Jan. 21, 1901. Serial No. 64,975. (No model.)

Claim.—A pump comprising a cylinder, having inlet and outlet valves, a headed piston operating in said cylinder, a supplementary hollow rod in which said piston is telescoped, a spring in said rod bearing against the head of said piston, and a latching in said rod for loosely engaging the head of said piston, whereby the motion-stroke of said piston is positive, and its operative stroke is yielding.

700,647. POWER-TRANSMISSION MECHANISM. JAMES HARTNER, Springfield, Vt. Filed Feb. 12, 1901. Serial No. 67,007. (No model.)

Claim.—1. The combination with a driving-shaft and a driven shaft, of an interposed friction mechanism comprising two friction members, one of which is bodily movable in line radial to the axis of the other member, said members having parallel ends and having concave and convex faces respectively, whereby the point of contact between said faces may be advanced toward the periphery of one member and simultaneously toward the axis of the other member, means for giving said movable member its described movement, and a device for holding said member at any desired position.

2. The combination with a driving-shaft and a driven shaft arranged in parallel, of a support movable about the axis of the driving-shaft, a friction member on said support, power-transmitting mechanism between said friction member and said driving-shaft, a friction member on the driven shaft, means for moving said support toward and from the driven shaft, and a ratchet for holding said support in any desired position.

3. The combination with a driving-shaft, of a support oscillatory about the axis of the said shaft, a head-lever connected to said support to oscillate it, a manually-operated ratchet for holding said head-lever in any desired position, a driven shaft parallel to the driving-shaft, a friction member on said driven shaft, and a friction member on said support, whereby the motion-stroke of said piston is positive, and its operative stroke is yielding.

the member on said driven shaft, and a friction member on said support actuated by the driving-shaft, and adapted to be brought into operative relation to said driven friction member to actuate the same at any of a variety of different speeds.

700,648. NOTE-BOOK. ALBERT L. HANSEN, Norfolk, Va. Filed Jan. 2, 1902. Serial No. 68,976. (No model.)

Claim.—1. The improvement in note-books herein described, comprising the base-plate deposed or hinged off at its opposite edges, provided with openings through which the ends of the bows may be passed and with fixed posts adjacent to said openings, the bows fitting alongside said fixed posts, and devices for securing the bows in connection with the base-plate, substantially as set forth.

2. In a device, substantially as described, the combination with the base-plate, of the half-round posts thereon, the bows having half-round transverse lapping alongside the said posts, and means for securing the bows, substantially as set forth.

3. The combination with the base-plate, and the posts thereon, of the bows interlocking with the posts, and devices for securing the bows to the base-plate, substantially as set forth.

4. The combination with the base-plate having openings through which the ends of the bows may project, the bows projecting at their ends through said openings and latch devices for securing the bows to the base-plate, substantially as set forth.

5. The combination with the base-plate having openings for the ends of the bows, and the posts adjacent to said openings, of the bows lapping alongside the posts and projecting through the openings in the base-plate, and latch devices beneath the base-plate for securing the bows, substantially as set forth.

6. The combination with a base-plate having openings for the ends of the bows and posts adjacent to said openings, the bows fitting alongside and interlocking with the posts and projecting through the openings in the base-plate, and the latch-plate beneath the base-plate and movable into and out of engagement with the bows, substantially as set forth.

7. The combination with the base-plate and the posts thereon, and notched in their upper ends, of the bows provided at its ends with transverse fitting alongside the posts and at the upper ends of said transverse shoulders having projections entering the notches of the posts, and means for securing the bows, substantially as set forth.

8. The combination of the base-plate provided with openings for the ends of the bows, the bows projecting at its ends through said openings, and the latch-plate beneath the base-plate and arranged to secure the bows, substantially as set forth.

9. The combination of the base-plate provided in its under side with a groove, and having openings for the ends of the bows, the bows projecting at its ends through said openings and the latch-plate opening in the groove in the under side of the base-plate and movable into and out of engagement with the bows, substantially as set forth.

10. The combination with the base-plate provided with openings for the bows and adjacent thereto with posts, the bows fitting at its ends alongside said posts and projecting through the openings in the base-plate, and the latch beneath the base-plate for securing the bows, substantially as set forth.

11. In a note-book, the combination of the base-board, provided with a transverse undercut groove, and the base-plate fitted to said groove and movable into and out of the same and provided with bows arranged transversely the length of the base-plate for securing the note-books, substantially as set forth.

700,649. REMEDIES FOR ANOXYGEN. ROBERT HANSEN, Berlin, Germany. Filed Feb. 24, 1902. Serial No. 69,000. (No model.)

Claim.—1. An an-oxygen cathode, consisting of cathodic decomposable by water and conducting substance incorporated in the body of the cathode, and a superficial coating of a body impervious to water.

2. An an-oxygen cathode, consisting of cathodic decomposable by water and conducting substance incorporated in the body of the cathode and a superficial coating of a body impervious to water.

3. An an-oxygen cathode, consisting of cathodic decomposable by water and conducting substance incorporated in the body of the cathode and a superficial coating of a body impervious to water.

4. An an-oxygen cathode, consisting of cathodic decomposable by water and carbon mixed therewith and a metallic wire embedded in the cathode, and for the purpose described.

700,650. ELECTRIC LAMP. OSWALD HUMBER, New York, N. Y. Filed Aug. 9, 1900. Renewed Jan. 17, 1902. Serial No. 60,120. (No model.)

Claim.—1. In an electric lamp, the combination with a series of compartments and a cover therefor, of a battery-cell located in each compartment, each cell having an anode of conducting material upon its one end connected with one element of the cell and surrounding the terminal of the other element which is centrally located in respect to the anodes and the same end of the cell, and contact-points contained in the compartments and so disposed as to contact with the anodes and terminals of the central elements of the several cells respectively, substantially as described.

2. In an electric lamp, the combination with a series of compartments and a cover therefor closing the ends of the compartments, of a battery-cell located in each compartment, each cell having an anode of conducting material upon its one end connected with one element of the cell and surrounding the other element thereof, which has a central element centrally located in respect to the cell, and spring-contact points so located in the ends of the compartments that the anodes and central elements of the several cells are held in contact with the respective contact-points by the cover, substantially as described.

3. In an electric lamp the combination with a casing having a series of metallic compartments and a metallic cover therefor closing the ends of the compartments, of an insulating lining in the said compartments, a battery-cell located in each compartment, each cell consisting of a cup-shaped vessel forming one element of the cell and another element centrally located therein, the open end of the vessel being closed by a coating of insulating material, the casing being surrounded by an anode electrically connected thereto, a lamp having its one terminal in electrical connection with the battery vessel in an end compartment and its opposite terminal in connection with the casing, a contact located in the said end compartment and making contact with the central element of the cell placed therein, two spring-contacts in one or more of the other compartments, making contact with the anodes and the central element of the cells contained therein respectively, a spring-contacts in the

last compartment of the casing making contact with the annulus of the battery contained therein, the said contact-points connecting the several battery-cells in series, and a contact-maker adapted to connect the central element of the cell in the last compartment with the casing, substantially as described.

4. The combination with a suitable conducting apertured casing, of a battery-cell contained therein, an insulating-lining between the cell and casing having overlapping apertured edges, the apertures in which register with each other and with the aperture in the casing, a conducting-strip partly contained within the lining of the casing and partly between the overlapping edges of the lining, an electric-lamp bulb having its one terminal in electrical connection with the casing and its other terminal projecting through the casing and insulating-lining into contact with said strip, and means for closing the circuit between the casing and the other element of the battery, substantially as described.

5. A lamp-casing consisting of a central rod having a threaded upper end and a series of metallic compartments grouped around it and secured thereto, a head secured to one of the compartments and containing a lamp-bulb, a cover for the said casing consisting of a metallic sheet with flanged sides to fit upon the exposed edges of the compartments, and a knob curving upon the central rod and forcing the cover into place, substantially as described.

6. The combination with a casing consisting of a plurality of compartments to receive battery-cells, a lamp-bulb means contained in one of the compartments for connecting one terminal thereof to one element of one of the cells, a cover for the casing, means carried by the cover for connecting the several cells together, and means for closing the circuit between the cells and the opposite terminal of the lamp-bulb, substantially as described.

7. The combination of a battery-casing having nested spring-pressed contact-points therein at one end thereof, and a battery-cell contained in the casing and having its two elements terminating respectively in a button and a surrounding annulus adapted to contact with the contact-points, substantially as described.

8. The combination in a battery-casing, of two spring-pressed contact-points, consisting each of a half of wire, at one end thereof and adjacent to each other and an insulating-cover for each of the contact-points consisting of a section of elastic tubing, substantially as described.

9. In an electric lamp the combination of a battery-cell having two elements and having a centrally-disposed contact-point and a surrounding annulus upon the same end thereof, substantially flush with each other, and connected respectively with the several elements of the cell, and a casing for the cell having contacts to contact with the central part and surrounding annulus of the cell, substantially as described.

700,851. NUT-LOCK. WILLIAM D. HUGHES, Greenville, N. Y., assigner of one-half to John T. Williams, Brooklyn, N. Y. Filed Oct. 12, 1901. Serial No. 79,357. (No model.)

Claim.—The combination with a nut, a bolt carrying a nut, and a lock-plate having a longitudinal groove and secured upon the bolt between the nut and nut, of a washer secured upon the bolt between the lock-plate and nut, the washer having its ends bent at right angles to fit in the groove and provided with an enlarged bearing-surface against which the nut bears preventing the washer from tilting upon the bolt and to hold the flanges in the groove, legs upon the washer, and a locking-bar having a nut-receiving opening and secured upon the legs.

700,852. BURGLAR-ALARM. CURRY JAMES, ALBANY, W. V. Filed Dec. 31, 1901. Serial No. 97,304. (No model.)

Claim.—1. A device of the class described comprising relatively fixed and movable contacts having means for holding them in normal and yieldable engagement, and a pivoted member connected with the movable contact for moving and releasing it when said member is moved pivotally, said pivoted member projecting at an angle to the path of movement of the movable contact for engagement by a door to move and hold it with the contacts out of engagement.

2. A device of the class described comprising a base having a fixed contact thereon, a pivoted contact-arm disposed for engagement with the fixed contact, a slide-bar with which the arm is connected, a spring engaged with the slide-bar to hold it yieldably with the contacts in engagement, a post, and a link pivoted to the post and to the slide-bar and arranged for engagement by a door to move and hold it against the action of the spring.

3. A device of the class described comprising a base having a fixed contact thereon, a movable contact-arm disposed for engagement with the fixed contact, a slide-bar with which the arm is operatively connected, a post in which the slide-bar is slidably engaged, a link pivoted to the post and slide-bar and adapted for engagement by a door to press it rearwardly, and a spring connected to the slide-bar and disposed to hold it yieldably with the contacts in engagement.

700,853. COVER FOR TUNNELS OR OTHER VEHICLES. FRANK L. JONES, Richmond, Va. Filed Oct. 3, 1901. Serial No. 77,992. (No model.)

Claim.—1. A cover for vessels comprising a cap having a thickened portion pendant therefrom and an opening or slot in said thickened portion the walls of said opening or slot forming gripping-jaws.

2. A cover for vessels comprising an elastic cap, a central portion pendant therefrom, a thickened portion at the lower end of the central portion, said thickened portion forming an annular ring or band and being of less diameter than the upper portion of the cap, a slot or opening in said ring or band, the side walls of said slot or opening forming gripping-jaws.

3. A cover for vessels comprising an elastic cap having a thickened lower portion, an enlargement or swell in said thickened portion, a slot or opening in said enlargement or swell, and jaws adjacent to said slot or opening adapted to grasp a spoon or other article.

4. A cover for vessels comprising an elastic cap, enlargements or swells in its periphery, a slot or opening in said enlargements or swells, and gripping-jaws adjacent to the slot or opening adapted to grasp a spoon or other article.

5. A cover for vessels comprising an elastic cap, provided with a vertical slot or slit in its periphery, forming gripping-jaws adapted to receive and grasp a spoon or other article.

6. A cover for vessels comprising an elastic cap, having a thickened lower end, an enlargement or swell in the periphery of said thickened end, a vertical slot or opening in the edge of said enlargement, a circular opening in the rear of said vertical slot and communicating therewith, and jaws adjacent to the vertical slot and circular opening, adapted to receive and secure a spoon or other article, the said cap being adapted to tightly grasp the upper edge of a vessel and render the same air-tight substantially as shown and described.

7. A cover for vessels comprising an elastic cap, a flange projecting horizontally therefrom, a slot or opening in said flange, elastic side walls

adjacent to said slot or opening forming elastic jaws to receive and grasp a spoon or other article.

8. A cover for vessels comprising an elastic cap, having a lower thickened edge, an enlargement or swell in said thickened portion, a vertical slot having beveled or rounded front faces, an enlarged opening in rear of said vertical slot, and communicating therewith, and elastic gripping-jaws adjacent to said vertical slot and opening, substantially as shown and described.

9. A cover for vessels comprising an elastic cap, an integral swell or enlargement in the periphery thereof, and slot or opening in said swell or enlargement forming gripping-jaws, adapted to receive and grasp a spoon or other article.

700,854. COLLAPSEABLE BARREL. DAVID E. JONES, Rockymount, N. C., assigner of one-half to Edmund E. Carr, Rockymount, N. C. Filed Jan. 25, 1902. Serial No. 91,841. (No model.)

Claim.—1. In a collapseable barrel, the combination with a body portion, of heads supported thereby, chains passing around said body portion and secured thereto, levers pivoted to said body portion and hooks carried by the levers and adapted to engage the links of said chains, substantially as described.

2. In a collapseable barrel, the combination with heads, of a body portion formed of staves, chains connecting said staves, levers carried by the staves adjacent one end of the chains, and hooks carried by the levers and adapted to engage the opposite links of the chains, substantially as described.

3. In a collapseable barrel, the combination with heads, of a body portion formed of staves, chains connecting said staves, pivoted levers carried by the staves adjacent the ends of the chains, hooks carried by the levers and adapted to engage the links at the opposite ends of said chains, and means for holding said levers in a downward position, substantially as described.

4. In a collapseable barrel, the combination with a body portion formed of staves, heads carried thereby, chains connecting said staves, detachable means for drawing the ends of the chains together, the said staves having openings on the outside of the heads, bolts passing through said openings and having one end screw-threaded, a clamping-nut on said screw-threaded end, and a pivoted head carried by the opposite end of the said bolt, substantially as described.

5. In a collapseable barrel, the combination with heads, of a body portion supporting said heads, said body portion composed of staves connected together by chains, pivoted levers carried by the staves adjacent the ends of the chains, hooks carried by the levers above their pivotal points and adapted to engage the opposite links of the chains, and spring-catches carried by the staves and adapted to hold the levers in a downward position, substantially as described.

6. In a collapseable barrel, the combination with heads, of a body portion composed of staves connected together by chains, removable clamping-bolts passing through the staves and extending transversely across the heads on the outside thereof, pivoted levers carried by the staves adjacent the ends of the chains, hooks pivotally connected to the levers above their pivotal points and adapted to engage the opposite ends of the chains and spring-catches carried by the staves back of the levers and adapted to hold the levers in a downward position, substantially as described.

7. In a collapseable barrel, the combination with heads, of staves forming a body portion, heads supported by said staves, chains passing around said staves and arranged with three links opposite each stave, staples securing the two outside links in each stave, pivoted levers carried by the staves adjacent the ends of the chains, hooks carried by the levers and

adapted to engage the opposite ends of the chains, and spring-catches adapted to hold the levers in a downward position, substantially as described.

8. In a collapseable barrel, the combination with heads, of staves forming a body portion and supporting said heads, chains passing around said staves, and arranged with three links opposite each stave, staples securing the two outside links to each stave, and means for drawing the ends of said chains together, substantially as described.

700,855. MANUFACTURE OF GOLF-BALLS. BRADSHAW KEMP-SMALL, Boston, Mass., assigner to The Kempshall Manufacturing Company, a Corporation of New Jersey. Filed Nov. 14, 1901. Serial No. 83,500. (No model.)

Claim.—1. A process in producing a playing-ball, consisting in applying a jacket of fibrous material to a core of solid material, insulating said jacket and core in segments of plastic material, heating and forcing said segments together so as to form a weld between them, and maintaining the impression while the shell cools and hardens.

2. A process in producing a playing-ball, consisting in winding twice or the like around a solid nucleus or core of elastic material, making a shell in segments of plastic material which approximate their final form, heating said segments and compressing them upon said wound nucleus or core so as to weld said segments together, and maintaining the compression while the welded segments cool and harden.

3. A process in producing a playing-ball, consisting in winding several layers of twice or the like around a core consisting of gutta-percha, heating said segments and forcing them together over said wound core so as to weld them to each other and also to place said core under compression, and maintaining the compression of the shell upon the core while the shell cools and hardens.

4. A process in producing a playing-ball, consisting of making a core consisting largely or wholly of gutta-percha, providing the same with a retaining-jacket of fibrous material, making cellular segments, heating said segments, forcing them over said jacketed core, welding them together, compressing the core, and maintaining the compression until the shell hardens.

700,856. SHELL-BLANK FOR PLAYING-BALLS. BRADSHAW KEMP-SMALL, Boston, Mass., assigner to The Kempshall Manufacturing Company, a Corporation of New Jersey. Filed Mar. 19, 1902. Serial No. 84,578. (No model.)

Claim.—1. A partial shell for a playing-ball, comprising a layer of plastic material lined with fabric.

2. A half-shell for a playing-ball, comprising layers of plastic material and layers of fabric in alternation, one of said fabric layers forming a lining for the half-shell.

3. A partial shell for a playing-ball, consisting of cellular fabric in which fabric is embedded.

4. A hemispherical shell-blank consisting of cellular fabric having a lining of fabric.

5. A hemispherical shell-blank consisting of piles of cellular fabric and piles of fabric, one of said fabric piles forming a lining for the shell, and all of said piles being compressed together.

6. A process in forming a shell-blank, consisting in compacting together under heat and pressure a ply of fabric and a ply of celluloid, maintaining the pressure until the celluloid cools and hardens, capping the material under heat and pressure, and maintaining the pressure until the celluloid cools and hardens.

7. A process in forming a shell-blank, consisting in compacting together under heat and pressure a ply of fabric and a ply of celluloid, maintaining the pressure until the celluloid cools and hardens, capping the material under heat and pressure, maintaining the pressure until the celluloid cools and hardens, and trimming off the surplus material.

8. A process in producing a playing-ball, consisting in compacting under heat and pressure piles of celluloid and alternate piles of fabric, maintaining the pressure until the celluloid cools and hardens, capping the material under heat and pressure, and maintaining the pressure until the celluloid rehardens.

9. A process in forming a partial shell for a playing-ball, consisting in capping under heat and pressure piles of fabric and celluloid, and maintaining the compression until the shell hardens.

10. A process in forming a half-shell for a playing-ball, consisting in capping under heat and pressure piles of fabric and celluloid, maintaining the compression until the shell hardens, and cutting off the surplus material.

11. A process in producing a shell-segment for a playing-ball, consisting in capping under heat and pressure piles of celluloid and alternate piles of fabric, and maintaining the pressure until the shell hardens.

12. A process in forming shell-blanks for playing-balls, consisting in capping piles of fabric and plastic material under heat and pressure so that the fabric forms a lining for the cap, and maintaining the pressure until the plastic material hardens.

13. A process in forming shell-blanks for playing-balls, consisting in capping piles of fabric and celluloid under heat and pressure so that the fabric forms a lining for the cap, and maintaining the pressure until the celluloid hardens.

14. A process in forming hemispherical shell-blanks for playing-balls, consisting in capping piles of fabric and celluloid under heat and pressure so that the fabric forms a lining for the cap, maintaining the pressure until the shell hardens, and trimming off the surplus material.

700,657. MANUFACTURE OF GOLF-BALLS. BREMER KEMP-
SHALL, Boston, Mass., assignor to The Kumpshall Manufacturing Com-
pany, a Corporation of New Jersey. Filed Mar. 19, 1908. Serial No.
60,977. (No model.)

Claim.—1. A process in producing a playing-ball, consisting in including a core of springy material in previously-formed spherical segments of fabric and plastic material, providing said segments with a cementing-coat, placing over said coating an outer layer of spherical segments, bringing said plastic material to a plastic condition, subjecting the whole to compression, and maintaining the compression while the shell hardens.

2. A process in producing a playing-ball, consisting in including a core of springy material in previously-formed spherical segments of fabric and plastic material, providing said segments with a cementing-coat, said segments being so placed that the joint in one layer runs crosswise of the joint in the other layer, bringing the plastic layers to a plastic condition, and subjecting the whole to compression.

3. A process in producing a playing-ball, consisting in including a core of springy material in previously-formed spherical segments of fabric and seasoned celluloid, coating said segments with a layer of green celluloid, placing over said coating an outer layer consisting of spherical segments of celluloid and fabric, heating said layers, subjecting the whole to compression, and maintaining the compression while the shell hardens.

4. A process in producing a playing-ball, consisting in including a core of springy material in previously-formed spherical segments of celluloid and fabric, covering said segments with a layer of celluloid, placing thereover a layer consisting of spherical segments of celluloid and fabric, subjecting the whole to heat and compression, and maintaining the compression while the celluloid cools and hardens.

5. A process in producing a playing-ball, consisting in including a core of springy material in previously-formed spherical segments of seasoned celluloid and fabric, coating said segments with a layer of green celluloid, placing over said coating an outer layer consisting of spherical segments of celluloid and fabric, the joint or seam in one layer running crosswise of the joint or seam in the other layer, heating said layers, and subjecting the whole to compression.

6. A process in producing a playing-ball, consisting in applying layers of celluloid and woven fabric to a core of springy material, subjecting the ball thus formed to heat and compression, and maintaining the compression while the shell hardens by cooling.

7. A process in producing a playing-ball, consisting in applying successive layers, each consisting of fabric and plastic material, upon a spherical core, cementing said layers together, and subjecting the whole to compression.

8. A process in producing a playing-ball, consisting in applying layers of plastic material and woven fabric to a core of springy material, subjecting the ball thus formed to heat and compression, and maintaining the compression while the shell hardens by cooling.

9. A process in producing a playing-ball, consisting in applying successive layers of fabric and celluloid upon a spherical core, cementing said layers together, and subjecting the whole to heat and compression.

10. A process in producing a playing-ball, consisting in forming a plurality of sets of hemispherical segments of celluloid and fabric, placing said segments upon a core of springy material so as to form a plurality of alternating celluloid and fabric layers, subjecting the whole to heat and compression, and maintaining the compression while the shell hardens by cooling.

11. A process in producing a playing-ball, consisting in forming hemispherical segments of celluloid and fabric, placing said segments upon a core of gutta-percha so as to form a plurality of layers, the joint or seam in one layer crossing a joint or seam in another layer, placing an incompletely-cured coating of celluloid between said layers, subjecting the whole to heat and compression to an extent to compress said core, and maintaining the compression while the shell cools and hardens.

12. A process in producing a playing-ball, consisting in including a core in a shell composed of successive layers of plastic material and fabric, at least one of said layers being previously formed and consisting of spherical segments, bringing the plastic layers to a plastic condition, subjecting the whole to compression, and maintaining the compression while the shell hardens.

13. A process in producing a playing-ball, consisting in including a core in previously-formed sets of hemispherical segments of plastic material compounded with fabric, so as to make a shell consisting of a plurality of layers, the segments being so placed that the joint in one layer crosses the joint in another layer, and subjecting the ball thus formed to heat and compression.

14. A process in producing a playing-ball, consisting in including a core in previously-formed sets of segments of plastic material and fabric, so as to make a shell, the segments being so placed that the joint in one layer crosses the joint in another layer, heating the plastic material, subjecting the whole to compression so as to weld the segments together at their edges, and maintaining the compression while the shell cools and hardens.

15. A process in producing a playing-ball, consisting in including a core in layers previously compounded of celluloid and fabric, at least one set of said layers consisting of spherical segments, subjecting the whole to heat and compression, and maintaining the compression while the shell hardens.

16. A process in producing a playing-ball, consisting in including a core in previously-formed layers each consisting of segments of celluloid and fabric, the segments being so placed that the joint in one layer crosses the joint in another layer, and subjecting the ball thus formed or assembled to heat and compression.

17. A process in producing a playing-ball, consisting in including a core of springy material in shell layers, at least one of said layers being previously formed and consisting of spherical segments of plastic material and fabric, bringing the plastic material to a plastic condition, subjecting the whole to compression to such an extent as to compress said core, and maintaining the compression while the shell hardens.

18. A process in producing a playing-ball, consisting in including a core consisting largely of gutta-percha in layers each consisting of previously-formed segments of plastic and textile material, the segments being so placed that the joint in one layer crosses the joint in another layer, subjecting the ball thus formed or assembled to heat and also compression to such an extent as to compress said core, and maintaining the compression until the shell cools.

19. A process in producing a playing-ball, consisting in including a core of gutta-percha in shell layers of celluloid and fabric, at least one of said layers being previously formed and consisting of spherical seg-

ments, heating the celluloid, subjecting the whole to compression, and maintaining the compression while the celluloid cools and hardens.

20. A process in producing a playing-ball, consisting in inserting a core of gutta-percha in previously-formed segments consisting of both celluloid and fabric as to make a shell consisting of a plurality of layers, the segments being so placed that the joint in one layer crosses the joint in another layer, and subjecting the ball thus formed or assembled to heat and compression, as to weld the segments at their edges.

21. A process in producing a playing-ball, consisting in inserting a springy core, in previously-formed spherical segments compounded of fabric and celluloid, coating said segments with cement, placing over said coating an outer layer of spherical segments of fabric and celluloid, and subjecting the whole to heat and compression.

22. A process in producing a playing-ball, consisting in inserting a core with a shell built up of fabric and celluloid, heating and compressing the shell, and maintaining the compression while the shell cools.

23. A process in producing a playing-ball, consisting in inserting a yielding core in a shell composed of at least two layers of celluloid and at least one intervening layer of woven fabric, and heating and compressing the shell.

700,658. PLAYING-BALL. BRADSHAW KIMBALL, Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Mar. 28, 1902. Serial No. 92,582. (No model.)

Claim.—1. A playing-ball comprising an inner sphere of metal and an outer sphere of celluloid, one of said spheres having integral hole and the other of said spheres having pin engaged by said hole.

2. A playing-ball comprising an inner metallic sphere having pin, and an outer celluloid sphere having integral hole which project into said pin.

3. A playing-ball comprising a hollow metal sphere provided with pin, and a celluloid shell open said sphere, said shell having integral hole which enter said pin.

4. A playing-ball, comprising a hard hollow core, a metal sphere thereon, and a hard shell interlocking with said sphere.

5. A playing-ball, comprising a core, a metal sphere thereon, and a celluloid shell interlocking with said sphere.

700,659. MANUFACTURE OF PLAYING-BALLS. BRADSHAW KIMBALL, Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Mar. 27, 1902. Serial No. 100,236. (No model.)

Claim.—1. The process herein described of making playing-balls, which consists in applying in alternation laminae of plastic and fibrous materials to a suitable core, causing said plastic material to soften or harden upon the ball, and finally completing the ball by compression.

2. The process herein described of making playing-balls, which consists in applying in alternation laminae of plastic and fibrous materials to a suitable core, causing each of said plastic laminae before the next fibrous lamina is applied, and finally compressing the structure.

3. A process in producing a playing-ball, consisting in coating a yielding core with celluloid solution, hardening said coating, and applying thereto a lamina of fibrous material.

4. A process in producing a playing-ball, consisting in coating a yielding core with celluloid solution, hardening said coating, applying thereto a lamina of fibrous material, subjecting the core thus formed to heat and compression, and maintaining the compression while the shell cools.

5. A process in producing a playing-ball, consisting in applying to a

previously-formed sphere a lamina of fibrous material coating said lamina with celluloid solution, hardening said coating, subjecting the ball thus formed to heat and compression, and maintaining the compression while the shell cools.

6. A process in producing a playing-ball, consisting in applying to a core in alternation laminae of fabric and laminae of material in a plastic condition, allowing each plastic lamina to harden before applying the next lamina, and then compressing and heating the whole.

7. A process in producing a playing-ball, consisting in applying successive layers of celluloid alternating with fabric upon a core, said celluloid being applied in plastic condition and hardened or softened upon the ball, and then subjecting said layers to simultaneous pressure and heat, and maintaining the pressure until the celluloid hardens.

8. A process in making a playing-ball, consisting in applying to a core, a plurality of layers one after another of fluid or plastic material, hardening one layer before another is applied, alternating said layers with laminae of fabric, subjecting the whole to heat and compression, and maintaining the compression while the shell cools.

700,660. GOLF-BALL. BRADSHAW KIMBALL, Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Apr. 11, 1902. Serial No. 102,604. (No model.)

Claim.—1. A playing-ball comprising a shell, a core having an annular groove, and a ring within the groove and along the joints of the shell and adapted to interlock the joint.

2. A playing-ball comprising a core having an annular groove, a plurality of shell-segments surrounding the core, and a ring located within the groove and interlocking the joints of the shell-segments.

3. In a playing-ball, interlocking means for the shell-segments comprising a continuous ring having flanges forming an annular groove and adapted to receive portions of the shell material of abutting edges of the shell.

4. A playing-ball comprising a spherical core, an annular groove in said core, a continuous ring in said groove, said ring having flanges and shell-segments interlocking the core and having their joints located between said flanges.

5. A playing-ball comprising a plurality of shell-segments holding a core under compression, and an independent ring adapted to internally interlock abutting edges of the shell-segments.

6. A playing-ball comprising hemispherical shell-segments enclosing a core under compression, and an independent ring having flanges adapted to interlock adjoining edges of the shell.

7. In a playing-ball, the combination of a filling, a shell thereon formed of plastic material, said segments being welded together, and a device applied to said segments and clenching them together.

8. In a playing-ball, the combination of a filling, a shell thereon formed of plastic material, said segments being welded together, and a device applied to said segments within said shell and clenching them together.

9. A playing-ball comprising a core and a shell thereon formed of segments of plastic material, said segments being welded together, and a device connecting said segments and interlocked with each thereof.

10. In a playing-ball, the combination with a springy core of a shell thereon formed of segments of plastic material, said segments being both welded and mechanically locked together.

11. In a playing-ball, the combination with a springy core of a celluloid shell thereon, said shell consisting of segments which are both welded and mechanically locked together.

12. In a playing-ball, the combination with a core of a shell thereon formed of segments of plastic material, said segments being welded together, and a device connecting said segments and locking into each thereof.

700,661. TRACTION-WHEEL. JOHN A. KIMMET, Jennings, La. Filed Aug. 21, 1901. Serial No. 74,012. (No model.)

Claim.—1. The combination with a traction-wheel rim formed with horizontally-angled openings, of a plurality of traction-chees each having arms extending at a right angle thereto, said arms adapted to extend through said openings, means for securing said chees in their folded position against the wheel-rim, and means for holding said arms against the inner side of the wheel-rim to project said chees.

2. The combination with a traction-wheel rim formed with horizontally-aligned openings, of a plurality of adjustable shoes each comprising a plate provided with arms extending through said openings, and each having a projecting eye, hooks for engaging said eyes, and catches adapted to engage the ends of said arms to secure the shoes in their projected position.

3. The combination with a traction-wheel rim formed with horizontally-aligned openings, of a plurality of adjustable shoes, each comprising a plate having arms extending through said openings, means for securing said shoes in their folded position against the wheel-rim, and catches pivotally secured to the inner side of the wheel-rim to engage said arms.

700,662. MACHINE FOR UPSETTING TUBES WITH ANNULAR CORRUGATIONS FOR RENDERING THEM FLEXIBLE. FRIDRICH W. KOTLER, Vienna, Austria-Hungary, assignor to Firm of Reinhardt & Bock, Vienna, Austria-Hungary. Filed Oct. 31, 1901. Serial No. 89,937. (No model.)

Claim.—1. In a machine of the class described, dies adapted to take into the corrugations of the tube and means to move the dies toward one another to upset the corrugations, substantially as set forth.

2. In a machine of the class described, two sets of dies adapted to take into the corrugations of the tube and means to move one set toward the other in the direction of the tube length to upset the corrugations, substantially as set forth.

3. In a machine of the class described, two pairs of dies adapted to be moved between the corrugations of the tubes and means to move one pair of dies toward the other in the direction of the tube length, substantially as set forth.

4. In a machine of the class described, two pairs of dies, means to move the dies into and out of engagement with the tube, and a reciprocable platen to move one pair of dies toward the other to upset the corrugations between them, substantially as set forth.

5. In a machine of the class described, two pairs of dies, one die of each pair located at one side of the tube, two cams each simultaneously moving two dies, means to yieldingly hold one pair of dies distanced from the other, and a reciprocable platen to move one pair of dies toward the other in the direction of the length of the tube, substantially as set forth.

6. In a machine of the class described, two pairs of dies, means to move them into and out of engagement with the tube, a platen to move one pair of dies in the direction of the length of the tube and means to intermittently feed the tube forward, substantially as set forth.

7. In a machine of the class described, a driving-shaft, a platen represented therefrom, dies to engage the tube, means to move the dies into and out of engagement with the tube and gear-driven from the driving-shaft, and means also gear-driven from the driving-shaft to intermittently position the tube with respect to the dies, substantially as and for the purpose set forth.

8. In a machine of the class described, the combination with dies and a platen acting thereon to upset the corrugations of a tube; of means to intermittently feed the tube to the dies comprising a screw-spindle, longitudinally movable, a nut thereon, a ratchet-wheel to move the nut and a pawl to intermittently move the ratchet-wheel, substantially as set forth.

9. In a machine of the class described, the combination with dies and a platen acting thereon to upset the corrugations of a tube; of an intermittently-operated feed device comprising a screw-spindle longitudinally movable, a sleeve, a two-part nut engaging the screw and carried by the spindle, a ratchet-wheel on the sleeve and means to intermittently move said ratchet-wheel, substantially as set forth.

10. In a machine of the class described, a driving-shaft, dies to engage the tube, means gear-driven from the driving-shaft to move the dies into and out of engagement with the tube, a platen to force the dies together lengthwise of the tube, a longitudinally-movable screw-spindle, a sleeve, a two-part nut carried thereby, and a ratchet-wheel thereon, a lever, a pawl thereon engaging the ratchet-wheel, a disk rotatable from the driving-shaft and a pin on said disk adapted to periodically move said lever and pawl to actuate the ratchet-wheel and nut to move the screw, substantially as set forth.

700,668. WORK-REST FOR GRINDING-MACHINES. ABRAHAM B. LARSEN, Waynesboro, Pa. Filed Feb. 12, 1902. Serial No. 89,787. (No model.)

Claim.—1. A work-rest for grinding-machines comprising a pivoted weight carrying bearing-blocks to engage the work mounted to oscillate on its pivot and move horizontally.

2. A work-rest comprising a pivoted weight with bearing-blocks to engage the work, said work-rest being mounted to practically balance on its pivot and move horizontally.

3. A work-rest for grinding-machines comprising a weight mounted on an axis to oscillate and to move horizontally and having bearing-blocks formed to engage the work to firmly secure said rest to move therewith.

4. A work-rest for grinding-machines comprising a pivoted weight having bearing-blocks thereon to engage the work, one of said blocks being held to the work by a yielding pressure, substantially as set forth.

5. A work-rest for grinding-machines, comprising a weight pivoted to oscillate and to move toward and from the grinding-wheel having two bearing-blocks thereon one of which has a face to embrace a part of the work and the other of which is held to the opposite side by a yielding pressure.

6. A work-rest comprising a pivoted weight balanced on its pivot and mounted to move horizontally to accommodate the work and having bearing-blocks to engage the work and hold said rest thereon, whereby the weight of said rest is added to the work to prevent vibration, while yielding freely to the surface of the work.

7. A work-rest for grinding-machines comprising a weight with bearing-faces engaging the work, said weight being mounted to swing and move horizontally.

8. A work-rest comprising a weight mounted to practically balance on its axis and to move horizontally and having bearing-blocks which are adapted to engage the work to hold said rest securely thereon during the operation.

9. In a work-rest the combination, of the frame, the weight mounted on rollers in a horizontal way in said frame, and the bearing-blocks adapted to engage the work to secure the weight thereon, substantially as set forth.

10. In a work-rest the combination, of the frame, the weight mounted on an axis in wheels, which wheels are mounted to run in horizontal ways in said frame, and blocks having flanges to engage the work and secure the rest thereon, substantially as set forth.

11. In a work-rest for grinding-machines, the combination, of the pivoted weight, the bearing-blocks, and the clamp for holding said weight rigid when desired, substantially as set forth.

12. In a grinding-machine, the combination, of the frame, the weight mounted on wheels on its axis in horizontal ways in the frame the bearing-block rigid with said weight to engage one side of the work, and the bearing-block mounted to be held to the other side of the work by a yielding pressure, substantially as set forth.

13. A work-rest comprising a pivoted balanced weight provided with means for holding it to the work.

700,664. HOT-AIR FURNACE. MAISON LEE and WILLIAM W. BRYAN, Agents, Ind., assignors to WILLIAM H. PIERCE, Agent, Ind. Filed Mar. 22, 1901. Serial No. 58,362. (No model.)

Claim.—1. In a hot-air furnace, metal plates set into the walls thereof forming a cold-air chamber, a combustion-chamber and a hot-air chamber, tubes traversing said combustion-chamber having their tops larger in area than their bottoms and extending above the floor of the hot-air chamber, a layer of clay having a wire-netting interposed therein covering the floor of said hot-air chamber to the level of the top of the hot-air tubes, a sheet of asbestos superposed over said clay, and openings cut in said asbestos over each tube having their edges turned down and held in the mouth of said tubes, substantially as shown and described.

2. In a hot-air furnace, metal plates set into the walls thereof forming a cold-air chamber, a combustion-chamber and a hot-air chamber, tubes traversing said combustion-chamber having their tops larger in area than their bottoms, a sheet of asbestos in said hot-air chamber covering the ends of said tubes, openings cut in said asbestos over the mouth of each tube, the edges of said openings turned down around the mouth of said tubes, and metal washers secured in the mouth of the tube to hold the edges of said openings therein, substantially as shown and described.

3. In a hot-air furnace, metal plates set into the walls thereof forming a cold-air chamber, a combustion-chamber and a hot-air chamber, a fire-pot in the combustion-chamber having vertically-extended walls to carry the products of combustion upward, smoke-flues interior of the side and rear walls and running horizontally therein near the floor of the combustion-chamber, and openings into said chamber to draw the products of combustion downward, substantially as shown and described.

4. In a hot-air furnace, a cold-air chamber, a hot-air chamber and a combustion-chamber, tubes connecting said cold-air and hot-air chambers, a sheet of asbestos in said hot-air chamber covering the ends of said tubes, openings cut in said asbestos over the mouth of each tube, the edges of said openings turned down and held in the mouth of said tubes, as and for the purposes shown and described.

5. In a hot-air furnace, the combination of a cold-air chamber at the base, an ash-pit therein inclosed on three sides by said cold-air chamber, a combustion-chamber containing a fire-pot having vertically-extended walls, a hot-air chamber over said combustion-chamber, tubes traversing said combustion-chamber for conveying air from the cold to the hot air chamber and heating during transit, said tubes surrounding the fire-pot on three sides and having the upper parts thereof flaring over the fire-pot, and horizontal flues in the side and rear walls of the furnace opposite the base of the combustion-chamber with outlets into said combustion-chamber, substantially as shown and described.

6. In a hot-air furnace, the combination with a cold-air chamber, a combustion-chamber and a hot-air chamber of horizontal smoke-flues in the side and rear walls of the combustion-chamber and situated near the base thereof, and openings from said smoke-flues into the combustion-chamber, the total area of the openings in each wall being equal to the

area of the plane through each smoke-flue cut at right angles to its direction, substantially as shown and described.

700,665. LINTER-CULTIVATOR. AUGUST LINDGREN, Moline, Ill., assignor to the Moline Plow Company, a Corporation of Illinois. Filed Feb. 18, 1902. Serial No. 94,607. (No model.)

Claim.—1. In a linter-cultivator the combination with a plurality of cultivating-frames, of a transverse connecting-bar, and a pivotal link connection between the frames and the bar.

2. In a linter-cultivator the combination with a plurality of frames, of a transverse connecting-bar, links jointed at their forward ends to the frames, and a jointed connection between the opposite ends of the links and the bar.

3. In a linter-cultivator the combination with a plurality of cultivating-frames, of a transverse connecting-bar, and parallel links connecting each frame with the bar.

4. In a linter-cultivator the combination with the cultivating-frames, of a transverse bar, parallel links connected at their front ends to the frames, and a connecting device joining the rear ends of the links and having a pivotal connection with the cross-bar.

5. In a linter-cultivator the combination with a plurality of frames, of a transverse connecting-bar, pairs of links jointed at one end to the frames, and a rod pivotally connecting the opposite ends of the links and pivoted between its ends to the cross-bar.

6. In a linter-cultivator the combination with a plurality of frames, of a transverse bar comprising two boards spaced apart, links jointed at their front ends to the frames and extending at their rear ends between the boards, and a jointed connection between the links and the boards.

7. In a linter-cultivator the combination with a plurality of frames having vertical bearings, of links having their forward ends extending vertically and mounted in the bearings and extending rearward, a transverse bar common to the frames, and jointed connections between the links and the bar.

8. In combination with a plurality of frames having transverse supporting-bases thereon, a transverse cross-bar and connecting-links jointed respectively to the frames and the bar and resting between their ends on the transverse supporting-bases.

9. In a linter-cultivator the combination with the cultivating-frame provided with a fixed transverse supporting-bar, of two end links jointed at their front ends to the frame and resting between their ends on the fixed bar, and a transverse cross-bar jointed to the rear ends of said links.

10. In a linter-cultivator the combination with a plurality of frames, of a transverse connecting cross-bar, links connecting the bar and frame and movable transversely with reference to the frame, and a fixed sup-

part on which the links rest between their ends; whereby the cast-bar is contained so as to yield vertically.

11. In a later-cultivator the combination with a plurality of cast-bar-frames, of a transverse cast-bar, and connecting devices between the frames and the bar having a free pivotal motion on a vertical axis.
12. In a later-cultivator the combination with a plurality of cast-bar-frames, of a transverse cast-bar, and connecting devices between the frames and the bar having a free pivotal motion on a vertical axis situated in front of the cast-bar.

700,666. STORAGE BATTERY. LEVI W. LAMAR, Boston, Mass., assignor to Fletcher W. Jewell, Boston, Mass. Filed Mar. 1, 1891. Serial No. 49,447. (No model.)

Claim.—1. In a storage-battery plate, in combination, the series of strips 10, 10, of conducting material, fitted for the reception of the supporting-rod, supporting-rod, also of conducting material tapering lengthwise, fitting within the slit of the said strips, and making contact with the edges of the slits, substantially as described.

2. In a storage-battery plate, in combination, the series of strips 10, 10, of conducting material having raised slotted bases, with the base of one strip fitting within the corresponding indentation of the next adjacent strip, and supporting-rod of conducting material tapering lengthwise, passing through the slits in the strips, and making contact with the edges of said slits, substantially as described.

3. In a storage-battery plate, in combination, the series of strips 10, 10, of conducting material having raised slotted bases, with the base of one strip fitting within the corresponding indentation of the next adjacent strip, and supporting-rod, of conducting material tapering lengthwise, passing through the slits in the strips, and making contact with the edges of said slits, substantially as described.

700,667. BASKET. ANTHONY M. HANSEN, Chicago, Ill. Filed Sept. 26, 1891. Serial No. 78,972. (No model.)

Claim.—1. The combination with a basket formed on its under surface with a depending frame or flange, of a plurality of pins depending from the under surface of the shoe, said pins being split longitudinally at their lower ends, bases surrounding the upper ends of the pins, and an elastic pad fitting said frame corrugated on its under surface and formed with openings to receive said pins and with recesses around said openings to receive said bases and the distended ends of the pins.

2. The combination with a basket formed on its under surface with a depending frame or flange, of a corrugated elastic pad having on edge flange fitting upon said frame, and formed with openings and with recesses around said openings on both its upper and under surfaces, and securing-pin projecting from the shoe within the frame and split at their lower ends, and strengthening-bases at the upper ends of the pins, said split pins being adapted to be clamped upon the pad.

700,668. FRUIT-JUICE EXTRACTOR. CLARA PARK, Denver, Colo. Filed Feb. 12, 1899. Serial No. 64,985. (No model.)

Claim.—1. In a device for extracting fruit-juice, the combination with a receptacle having a bottom provided with openings to allow the juice of the fruit to pass through, a cross-piece mounted on top of the receptacle and provided with a threaded opening, a plunger adapted to enter the receptacle and provided with an opening in its base through which the mouth of the nut or bag containing the fruit, may be drawn, and adapted to close said mouth, and a screw-stem connected with the plunger and threaded in the cross-piece at the top of the receptacle, substantially as described.

2. In a fruit-juice extractor, the combination with a receptacle having a bottom provided with openings, said bottom being raised above the lower bottom edge of the side walls of the receptacle, a cross-piece removably mounted on top of the receptacle and having a threaded opening, retaining device mounted on the receptacle to receive the cross-piece on-tressline, a screw-stem threaded in the cross-piece, and a plunger made fast to said stem, the plunger having an opening to receive the mouth of the nut containing the fruit, and constructed to close said mouth during the fruit-extracting operation, substantially as described.

3. In a device of the class described, the combination with a receptacle having a bottom composed of parallel wires raised above the lower edge of the side wall, which is provided with openings beneath the said bottom, a plunger adapted to enter said receptacle, the plunger having an opening adapted to receive and close the mouth of a nut, a screw-stem attached to the plunger, and a cross-piece mounted on the receptacle, in which cross-piece the screw-stem is threaded, substantially as described.

4. In a fruit-extractor, the combination with a receptacle having a bottom opening to allow juice to pass through, a plunger adapted to enter the receptacle, having parallel cross wires or plates, and an opening to receive the mouth of the nut containing the fruit, a screw-stem attached to said plunger, and a cross-piece or bar mounted on the upper edge of the receptacle, in which cross-piece the screw-stem is threaded.

5. The combination of a receptacle having a bottom provided with openings, a plunger adapted to enter said receptacle, and composed of a base, a hub and upwardly-projecting arms connecting the base and hub; a screw-stem attached to the hub, and a cross-piece mounted on top of the receptacle and in which place the screw-stem is threaded.

6. In a fruit-juice-extracting device, the combination of a receptacle having a bottom opening to allow the fruit-juice to pass through, a plunger located in said receptacle above said bottom, a screw-stem attached to the plunger, a cross-piece mounted on top of the receptacle whose upper edges are beveled, the cross-piece having hooks engaging said bevel, and provided with a threaded opening through which the screw-stem passes, and springs located on opposite sides of the top of the receptacle and adapted to receive the cross-piece extrinsically and retain the said piece in place, the head of the top of the receptacle being set away to permit the removal of the cross-piece, substantially as described.

7. In a fruit-juice extractor, the combination of a receptacle, having a bottom composed of parallel wires, a plunger located in said receptacle above the bottom and composed of an outer ring connected by parallel cross-wires, a small ring located between the cross-wires, a hub located above the cross-wires, and curved arms connecting the outer ring and the hub; a screw-stem attached to the hub, a cross-piece mounted on top of the receptacle, in which place the screw-stem is threaded, and a crank attached to the upper extremity of said stem, substantially as described.

700,669. STOP-VALVE FOR BARRED-CHAINS. JOHN B. BARNES, Denver, Colo. Filed Sept. 22, 1891. Serial No. 78,988. (No model.)

Claim.—A stop-valve attachment for barbed-chains comprising

two corresponding clamping members having depending parallel parts, horizontal parts extending outwardly in opposite directions from the upper extremities of the depending parts, and at right angles to the latter, parallel opposing parts extending upwardly from the horizontal parts, disks applied to the respective upwardly-projecting parts, rivets holding the respective disks in place and protruding on the faces of the disks to form holding-heads, and covers passing through registering openings formed in the depending parts and threaded in one of said parts.

700,670. ELECTROLYTIC REDUCTION OF NITRO OR OTHER COMPOUNDS. MAX BUCHNER, Mannheim, Germany, assignor to The Firm of C. F. Reibinger & Söhne, Mannheim-Walldorf, Germany. Filed Nov. 18, 1898. Serial No. 737,494. (No specimens.)

Claim.—1. The process of reduction which consists in introducing a substance capable of being reduced by tin into an electrolyte capable of dissolving tin, and passing an electric current through the same in the presence of tin.

2. The process of reducing a nitro compound which consists in introducing such compound into an electrolyte capable of dissolving tin, and passing a current through the same in the presence of tin.

3. The process of reduction which consists in introducing a substance, capable of being reduced by tin into an electrolyte capable of dissolving tin, and passing an electric current through the same in the presence of a tin cathode.

4. The process of reducing a nitro compound which consists in introducing such compound into an electrolyte capable of dissolving tin, and passing an electric current through the same in the presence of a tin cathode.

5. The process of reduction which consists in introducing a substance capable of being reduced by tin into an electrolyte capable of dissolving tin, and passing an electric current through the same in the presence of tin and at the same time stirring and cooling.

6. The process of reduction which consists in introducing a substance capable of being reduced by tin into an electrolyte capable of dissolving tin, and passing an electric current through the same in the presence of tin and at the same time stirring and cooling.

7. The process which consists in introducing a substance, which is reducible, and an anion into an acid electrolyte capable of dissolving tin, and passing an electric current through the same in the presence of a tin cathode.

8. The process which consists in introducing a substance which is reducible to an anion into an alkaline acid electrolyte capable of dissolving tin and passing an electric current through the same in the presence of a tin cathode while stirring and cooling.

9. The process which consists in introducing a nitro compound to be reduced into a cathode-bath containing hydrochloric acid and in which is arranged a tin cathode and passing an electric current through the bath.

10. The process which consists in introducing a nitro compound to be reduced into an alkaline cathode-bath containing hydrochloric acid, and in which is arranged a tin cathode, passing an electric current through said bath and stirring and cooling the same.

11. The process which consists in introducing a nitro compound into a bath containing a stannous compound and hydrochloric acid and having a cathode arranged therein and passing an electric current through the bath while stirring and cooling the same.

12. The process which consists in introducing a nitro compound into a cathode-bath containing hydrochloric acid and a stannous salt and having a cathode arranged therein, and passing an electric current through the bath while stirring and cooling.

700,671. REDUCTION OF ARSO COMPOUNDS. MAX BUCHNER, Mannheim, Germany. Filed Sept. 24, 1898. Serial No. 73,500. (No specimens.)

Claim.—1. The process of reducing arsenic compounds which consists in passing an electric current through such arsenic compounds dissolved or suspended in an electrolyte fluid capable of dissolving tin in the presence of tin, the arsenic compound and tin being arranged in the cathode-compartment.

2. The process of reducing arsenic compounds which consists in passing an electric current through such arsenic compounds dissolved or suspended in an electrolyte fluid containing tin, the arsenic compound and tin being arranged in the cathode-compartment.

3. The process of reducing arsenic compounds which consists in passing an electric current through such arsenic compounds dissolved or suspended in an electrolyte fluid capable of dissolving tin in the presence of tin and at an elevated temperature, the electrolyte fluid being capable of dissolving tin and the tin and arsenic compound being arranged in the cathode-compartment.

4. The process of reducing arsenic compounds which consists in passing an electric current through such arsenic compounds dissolved or suspended in an electrolyte fluid capable of dissolving tin containing tin and at an elevated temperature, the arsenic compound and tin being arranged in the cathode-compartment.

5. The process of reducing arsenic compounds which consists in charging the cathode-space of an electrolytic cell with a mixture of the arsenic compound with hydrochloric acid and water and passing the electric current there-through in the presence of tin.

6. The process of reducing arsenic compounds which consists in charging the cathode-space of an electrolytic cell with a mixture of the arsenic compound and powdered tin with water and hydrochloric acid and then passing the electrolytic current through the mixture.

700,672. REDUCTION OF NITRO COMPOUNDS. MAX BUCHNER, Mannheim, Germany. Filed Sept. 24, 1898. Serial No. 73,501. (No specimens.)

Claim.—1. The process of reduction which consists in introducing a reducible substance into the acid electrolyte contained in the cathode-space of an electrolytic cell and passing a current through the same in the presence of copper, the electrolyte being one capable of reducing the copper to the tin condition.

2. The process of reducing a nitro compound which consists in introducing such compound into the acid electrolyte contained in the cathode-space of an electrolytic cell and passing a current through the same in the presence of copper, the electrolyte being one capable of reducing the copper to the tin condition.

3. The process of reduction which consists in introducing a reducible substance into the acid electrolyte contained in the cathode-space of an electrolytic cell and passing a current through the same in the presence of a copper cathode, the electrolyte being one capable of reducing the copper to the tin condition.

4. The process of reducing a nitro compound which consists in introducing such compound into the acid electrolyte of the cathode-space of an electrolytic cell and passing an electric current through the same in the presence of a copper cathode, the electrolyte being one capable of reducing the copper to the tin condition.

5. The process of reduction which consists in introducing a reducible substance into an acid cathode-bath containing a compound of copper and passing an electric current through said bath, the electrolyte being one capable of reducing the copper to the tin condition.

6. The process of reduction which consists in introducing a reducible substance into an acid cathode electrolyte and passing an electric current through the same in the presence of copper and at the same time stirring and cooling, the electrolyte being one capable of reducing the copper to the tin condition.

7. The process which consists in introducing a substance which is

reducible to an amine into an acid cathode-bath in which is arranged a copper cathode and passing an electric current through the same.

8. The process which consists in introducing a substance which is reducible to an amine into an alcoholic-acid cathode-bath in which is arranged a copper cathode and passing an electric current through the same while stirring and cooling.

9. The process which consists in introducing a nitro compound to be reduced into a cathode-bath containing hydrochloric acid and in which is arranged a copper cathode to the action of an electric current.

10. The process which consists in introducing a nitro compound into a cathode-bath containing a cuprous compound and hydrochloric acid and having a cathode arranged therein and passing an electric current there-through.

11. The process which consists in introducing a nitro compound into a cathode-bath containing hydrochloric acid and a cuprous salt and having a cathode arranged therein, and passing an electric current there-through while stirring and cooling.

700,678. MANUFACTURE OF CERAMIC PRODUCTS. MAX BOEHRER, Mannheim, Germany. Filed Apr. 24, 1901. Serial No. 57,364. (No specimens.)

Claim.—1. The process of manufacturing ceramic products, which consists in combining previously-melted aluminium oxide with a plastic ceramic substance.

2. The process of manufacturing ceramic products for chemical purposes, which consists in mixing comminuted previously-melted aluminium oxide with comminuted plastic substances, such as kaolin.

3. The process of manufacturing ceramic products for chemical purposes, which consists in mixing comminuted previously-melted aluminium oxide with a plastic ceramic substance, such as kaolin, and adding to the whole the requisite amount of water.

4. The process of manufacturing ceramic products, which consists in mixing divided previously-melted aluminium oxide with a comminuted ceramic substance, such as kaolin, then adding the requisite amount of water and molding or forming the mixture into the required shapes.

5. The process of manufacturing ceramic products, which consists in mixing divided previously-melted aluminium oxide with a comminuted ceramic substance, such as kaolin, then adding the requisite amount of water and molding or forming the mixture into the required shapes and drying the mixture.

6. The process of manufacturing ceramic products, which consists in mixing divided previously-melted aluminium oxide with a comminuted ceramic substance, such as kaolin, then adding the requisite amount of water, molding or forming the mixture into the required shapes, drying and firing or burning the same.

7. The process of manufacturing ceramic products for chemical purposes, which consists in mixing together two parts by weight of comminuted previously-melted aluminium oxide with substantially one part by weight of divided kaolin and adding the requisite amount of water to form a plastic mass.

8. The process of manufacturing ceramic products for chemical purposes, which consists in mixing together two parts by weight of comminuted previously-melted aluminium oxide with substantially one part by weight of divided kaolin, adding the requisite amount of water to form a plastic mass and molding and drying the whole.

9. The process of manufacturing ceramic products for chemical purposes, which consists in mixing together two parts by weight of corundum powder with about one part by weight of levigated kaolin, adding the requisite amount of water, molding, drying and firing the mass.

10. As a new ceramic compound, previously-melted aluminium oxide mixed with a plastic ceramic substance, such as kaolin in the proportions substantially as hereinbefore set forth.

11. A new ceramic compound for chemical purposes consisting of corundum mixed with kaolin in the proportions substantially as hereinbefore set forth.

700,674. GARMENT. JAMES H. BURY, Springfield, Mass., assignor, by means assignment, to Cuno Shirt Coat Company, New York, N. Y., a Corporation of New York. Filed Sept. 4, 1900. Serial No. 24,908. (No model.)

Claim.—A coat comprising a portion *a*, arranged to be normally closed over the breast from the neck downward a depending back portion *b*, two complementary front flaps formed by cutting away the lower part of the front portion *a*, and an abdominal shirt portion *c* secured at its upper edge to the inside of the front portion *a*, and adapted to be worn inside of the trousers, substantially as described.

700,674.

700,675. MOP-HEAD. EDWARD R. CAMPBELL, Bakersfield, Cal., assignor of one-half to Melville H. Wangerheim, Bakersfield, Cal. Filed Feb. 2, 1902. Serial No. 92,436. (No model.)

Claim.—1. In a mop-head, the combination with the cross-head and yoke, of a ring to which the ends of the yoke are attached, and a handle, said ring and handle having thereon, the one a series of ratchet-teeth, and the other a stud for engaging said teeth, the ratchet-teeth pointing tangentially or laterally and being freed from said stud by a rotary relative movement of the ring and handle, substantially as described.

2. In a mop-head, the combination with the cross-head, yoke and handle, of a runner secured to the yoke, said runner having thereon a rack having teeth pointing laterally or tangentially, and a stud on said handle to engage said rack, substantially as described.

3. In a mop-head, the combination with a cross-head, yoke and handle, of a runner comprising a piece having a rack formed thereon, and having ears, and a band having ears, the ends of the yoke being hooked to engage the ears of said piece and band, and a stud on said handle engaging said rack, substantially as described.

4. In a mop-head, in combination with the handle, yoke, and means for regulating the yoke, a cross-head comprising a cross-piece formed of sheet metal bent into a U shape to form a trough, and a flange or sleeve stamped out of sheet metal and bent into a cylindrical form, two of its edges being brought around close to each other, and the whole being secured to the handle, the upper end of the sleeve so formed being bent over on opposite sides toward each other to form hooks passing over opposite edges of the trough, substantially as described.

700,676. ELECTRIC ELEVATOR. JOSEPH CHANDLER, Minneapolis, Minn., assignor of one-half to Patrick H. Morley, Minneapolis, Minn. Filed Sept. 2, 1901. Serial No. 74,300. (No model.)

Claim.—1. In an electric elevator, the combination with the wheel thereof, and the endless rope operating the same, of a crank-pin affixed in the said wheel, a connecting-rod mounted thereon, a spring actuating the said connecting-rod, and a stop for limiting the travel of the said pin, arranged substantially as shown and for the purposes specified.

2. In an electric elevator, the combination with the wheel thereof, and an electric switch actuated thereby, of a crank-pin affixed in the said wheel, a connecting-rod journaled thereon, a spring actuating the said

connecting-rod, and a stop to limit the travel of the said crank-pin; substantially as shown and for the purposes specified.

700,677. SELF-PLAYING ATTACHMENT FOR MUSICAL INSTRUMENTS. JAMES CORVILL, Detroit, Mich., assignor to FAYARD Organ Company, Detroit, Mich., a Corporation of Michigan. Filed May 31, 1901. Serial No. 92,612. (No model.)

Claim.—1. In a self-playing attachment for musical instruments, the combination of a base and wind-pumping device mounted thereon, of an action above said base, a series of key-actuating levers, and a common means for adjusting said levers to different horizontal planes for playing of any height within the range of the adjustment thereof, and maintaining at all points of adjustment their operative connection to the action.

2. In a self-playing attachment for musical instruments the combination of a base and wind-pumping device mounted thereon, of a pneumatic-action above said base, the series of key-actuating levers or strikers, a bar to which said levers are fulcrumed, a common means for vertically adjusting said bar to any height above the base within the range of adjustability, while maintaining the strikers in operating position and in operative connection with the action.

3. In a self-playing attachment for musical instruments the combination of a base, wind-pumping device mounted thereon, a casing extending upward from said base, a pneumatic-action located therein, a series of key-actuating strikers in operative relation to said action, and a common means for adjusting said strikers to any operating heights from the base, within the range of adjustability, such adjusting means holding the parts at every point of adjustment.

4. In a self-playing attachment for musical instruments the combination of a base, a wind-pumping device thereon, a casing, an action in the casing, a series of key-strikers adapted to be operated by the action

and a common support for said strikers adjustable to any operating height above the base within the range of the adjustability thereof.

5. In a self-playing attachment for musical instruments, the combination of a casing, an action therein and wind-pumping device, of a series of key-actuating levers, a common fulcrum-bar upon which said levers are supported and means for adjusting said fulcrum-bar and thereby the levers to any height within the range of the adjustability thereof, and a connection between the levers and the operating device of the action which is maintained at all points of adjustment.

700,678. DRILLING-MACHINE. ROBERT M. DOWNE, Beaver Hills, Pa., assignor to the Keystone Driller Company, Beaver Hills, Pa. Filed Apr. 24, 1901. Serial No. 97,216. (No model.)

Claim.—1. In a drilling-machine, the combination with a pivoted walking-beam for operating a drill, of means for oscillating the walking-beam, and a counterbalance for the walking-beam, comprising means for opposing a torsional resistance to the movement of the walking-beam, said means having its axis of oscillation substantially coincident with that of the pivot of the beam.

2. In a drilling-machine, the combination with a pivoted walking-beam for operating a drill, of means for oscillating the walking-beam, and a counterbalance for the walking-beam, comprising means for opposing a torsional resistance to the movement of the walking-beam, said means engaging the walking-beam contiguous to its pivot and having its axis of oscillation substantially coincident with that of the pivot of the beam.

3. In a drilling-machine, the combination with a pivoted walking-beam for operating a drill, of means for oscillating the walking-beam, and a counterbalance for the walking-beam, comprising means for opposing a torsional resistance to the movement of the walking-beam, said means engaging the walking-beam on opposite sides of its pivot and having its axis of oscillation substantially coincident with that of the pivot of the beam.

4. In a drilling-machine, the combination with a pivoted walking-beam for operating a drill, of means for oscillating the walking-beam, and a counterbalance for the walking-beam, comprising means for opposing a torsional resistance to the movement of the walking-beam, said means including flexible devices engaging the beam on opposite sides of its pivot, the axis of oscillation of each flexible device being coincident with that of the pivot of the beam.

5. In a drilling-machine, the combination with a pivoted walking-beam for operating a drill, of means for oscillating the walking-beam, and a counterbalance for the walking-beam, comprising means for opposing a torsional resistance to the movement of the walking-beam, said means including flexible devices engaging the beam on opposite sides of its pivot, the axis of oscillation of each flexible device being coincident with that of the pivot of the beam, and means for regulating the tension of the flexible devices.

6. In a drilling-machine, the combination with spaced supports, of a pivoted walking-beam located between the supports, and means for opposing torsional resistance to the movement of the walking-beam, said means comprising a rope or cable secured to the spaced supports and having portions engaging the beam on opposite sides of its pivot, the terminals of said rope or cable being adjustably secured together whereby its tension may be regulated.

7. In a drilling-machine, the combination with spaced supports, of a walking-beam pivoted between the supports, and a flexible element extending across the space between and connected to the supports, said element extending transversely of and engaging the walking-beam to form a resistance against the movement of the same.

8. In a drilling-machine, the combination with spaced supports, of a walking-beam pivoted between the supports, a flexible counterbalance element extending across the space between and connected to the supports, said element being located transversely of and engaging the walking-beam to form a resistance against the movement of the same, and means for regulating the tension of said counterbalance.

9. In a drilling-machine, the combination with spaced supports, of a walking-beam pivoted between the supporting-bars, a flexible element connected to said supports, said element extending transversely of and engaging the walking-beam on opposite sides of its pivot to form a resistance against the movement of said beam in either direction, and means for regulating the tension of said counterbalance.

10. In a drilling-machine, the combination with spaced supporting-bars, of bearings located on the opposing faces of said bars, a walking-beam located between said bars and having its pivot mounted in the bearings thereof, and a flexible element also secured to the bearings and arranged transversely across and secured to the beam to form a resistance against the movement of the same.

11. In a drilling-machine, the combination with spaced supporting-bars, of bearings located on the opposing faces of said bars, a walking-beam located between the bars and having its pivot mounted in said bearings, a flexible rope also secured to the bearings and arranged transversely across the beam, said rope being secured to the walking-beam on opposite sides of its pivot, and means for adjustably securing the ends of the rope together to regulate the tension of the same.

12. In a drilling-machine, the combination with spaced supports, of a pivoted walking-beam located between the supports, and a flexible rope or cable secured at its opposite ends to the supports, said rope or cable being located across and secured to the walking-beam.

13. In a drilling-machine, the combination with spaced supports, of a walking-beam pivoted intermediate for ends and located between the supports, and a flexible rope or cable having portions arranged transversely across the walking-beam on opposite sides of its pivot, said portions being secured to the supports.

14. In a drilling-machine, the combination with a pivoted walking-beam, of an operating-wheel for the walking-beam provided with a plurality of spaced sockets, a plate journaled upon the wheel at one side of its axis of rotation and adapted to pass over the sockets, a crank-pin carried by the plate, a pitman connecting the walking-beam and the crank-pin, and means carried by the plate and engaging the sockets for securing the crank-pin to said plate and holding the plate against movement on the wheel.

15. In a drilling-machine, the combination with a pivoted walking-beam, of an operating-wheel for the walking-beam, a plate journaled upon the wheel at one side of its axis of rotation, said wheel being provided with a plurality of sockets located in concentric relation to the journal-axis of the plate, and concentric to the journal-axis of the wheel, a crank-pin carried by the plate and movable into and out of alignment with the journal-axis of the wheel, a pitman connecting the walking-beam to the crank-pin, and a set-screw passing through the crank-pin and the plate and movable into and out of the sockets of the wheel, whereby said plate and wheel are held against relative movement.

16. In a drilling-machine, the combination with a frame including a derrick, of a rigid push-rod located longitudinally of and slidably mounted upon the derrick, a crown-pulley carried by the push-rod, a walking-beam having a detachable pivotal connection with the lower end of the rod, said rod being capable of a lateral movement when detached, a stationary support for the rod when detached, said support being located upon the frame, and means for oscillating the walking-beam.

17. In a drilling-machine, the combination with a driving-shaft, of a reel, means for operatively connecting said shaft and reel, said means including a clutch, the two members of which are mounted on the driving-shaft, one of said members being loosely mounted and having a geared connection with the reel, the other being arranged to turn with the shaft and slidable into and out of engagement with the first-named member, a brake for holding the loosely-mounted member against movement, and a lever having connection with the slidable member and the brake to successively move one into and the other out of operative position.

18. In a drilling-machine, the combination with a driving-shaft, of a reel, means for operatively connecting said shaft and reel, said means including a clutch, the two members of which are mounted on the driving-shaft, one of said members being loosely mounted and having a geared connection with the reel, the other being arranged to turn with the shaft and slidable into and out of engagement with the first-named member, a brake for holding the loosely-mounted member against movement, said brake comprising a pair of standards located on opposite sides of the member, a pivoted controlling-lever, a link connection between the controlling-lever and the slidable member of the clutch, and a toggle connection between the brake-standards and the link.

19. In a drilling-machine, the combination with a driving-shaft, of a reel, means for operatively connecting said shaft and reel, said means including a clutch comprising two elements mounted upon the driving-shaft, a movable brake for holding the reel against movement when uncoupled from the shaft, a pivoted operating-lever having connection with the clutch and brake, whereby said clutch and brake may be successively moved respectively into and out of operative relation, and means for adjusting the brake to compensate for wear.

20. In a drilling-machine, the combination with a reel, of a brake for the reel including a peripheral rim having a connection with said reel and movable therewith, a pair of standards located on opposite sides of the rim, a controlling-lever, toggle-links pivotally connected to the standards and to each other, and another link connected to both toggle-levers at their juncture and to the controlling-lever.

21. In a drilling-machine, the combination with a supporting-frame, of a driving-shaft and a driven shaft both journaled upon the frame and located in substantial parallelism, said driven shaft having a reel, means for operatively connecting the shafts, said means including a clutch comprising separate members both of which are mounted upon one of the shafts, one of said members being loosely mounted and having a geared connection with the other shaft, the other member being arranged to turn with the shaft and slidable into and out of engagement with the first-named member, a brake for holding the loosely-mounted member against movement, and common controlling means connected to the brake and movable clutch member for successively moving the brake into and the slidable clutch member out of their respective engagements and vice versa.

22. In a drilling-machine, drill-operating mechanism including a walking-beam, a pivot extending transversely across said beam, a counterbalance comprising a flexible element also extending transversely across the beam, and a keeper-block secured to the beam and embracing both the pivot and the counterbalance to hold them in place upon said beam.

700,679. GRANT-PLANE OR ANALOGOUS TOOL. EMERY E. BERNHARDT and FRED L. BERNHARDT, Newark, N. J., and BLAIR G. BERNHARDT, Elmhurst, N. Y., assignors to Gould & Bernhardt, Newark, N. J., a Corporation of New Jersey. Filed June 12, 1901. Serial No. 64,572. (No model.)

Claim.—1. In a crank-planner or shaping-machine having a reciprocating ram, the combination, with a driving-disk and an eccentric crank-plate fitted to the face of said disk, the disk and plate being overhung from the same bearing and the crank-plate being furnished with a crank-pin and connections to a reciprocating ram, of pins projected respectively from the driving-shaft and the crank-plate and connected by a link, whereby the uniform motion of the driving-disk produces a variable motion of the crank-plate, substantially as herein set forth.

2. In a crank-planner or shaping-machine having a reciprocating ram,

the combination, with a driving-disk and an eccentric crank-plate fitted to the face of each disk, the disk and plate being overhung from the same bearing and the crank-plate being furnished with a crank-pin and connections to a reciprocating ram, of a pin projected from the outer side of the crank-plate, a link pivoted thereon and a slot in the crank-plate with pin upon the link projected through each slot and attached to the driving-disk, whereby the uniform motion of the driving-disk produces a variable motion of the crank-plate.

3. In a crank-placer or shaping-machine having a reciprocating ram, the combination, with a driving-disk having peripheral teeth to rotate the same, and an eccentrically-pivoted crank-plate fitted to the face of each disk, and having a crank-pin with block pivoted thereon, the ram D with pitman G pivoted positively thereto and having slot G' fitted to the crank-pin block, and the laterally-projecting link I jointed to the bottom of the pitman and to a fixed bearing upon the frame, as and for the purpose set forth.

4. In a crank-placer or shaping-machine, the combination, with the driving-disk and eccentric plate linked thereto, as set forth, and having the crank-pin with block pivoted thereon, of the ram D having the pitman G pivoted positively thereto and having slot G' fitted to the crank-pin block, K, the laterally-projecting link I jointed to the bottom of the pitman and to a fixed bearing upon the frame, and the upper end of the pitman having the eye J' held at a uniform distance from the bottom of the ram by the pitman connection thereto, and adapted for the passage of a shaft or work-piece to the tool, substantially as herein set forth.

5. In a crank-placer or analogous tool having a work-table with a feed-screw to feed each table, and an oscillating lever to actuate each feed-screw, the combination, with each part, of a disk having a cam-groove face, a bearing projected at right angles to the disk, a feed-shaft fitted to the bearing and provided with feed-crank and crank-pin upon its outer end connected with the oscillating lever, and the shaft having upon its inner end an arm with block or roll fitted to the cam-groove, substantially as herein set forth.

6. In a crank-placer having a reciprocating ram in the top and slot-planes for reciprocating the same, the combination with the ram and pitman, of a bearing upon the frame at one side of the pitman, the driving-disk journaled in such bearing and provided adjacent to the frame with the cam-groove J, the eccentric plate fitted to its face and provided with crank-pin connected to each pitman, and the means for actuating a feed mechanism by the driving-disk, comprising the bearing J' fitted detachably to the frame with an aperture in the frame at the inner end of each bearing, the feed-shaft fitted to the bearing and provided with feed-crank and crank-pin upon its outer end and the shaft being extended into each aperture and provided with an arm having a block fitted to the cam-groove, whereby the feed-crank is oscillated by the arm at each rotation of the driving-disk, substantially as herein set forth.

7. In a crank-placer or shaping-machine having a ram, a slotted pitman, a driving-disk and connections from the disk to each pitman for reciprocating the ram, the combination, with the frame, of a bearing, the driving-disk journaled in such bearing and provided with a cam-groove adjacent to the frame, a feed-shaft bearing fitted detachably, and the frame having an aperture at the inner end of each bearing, a feed-shaft with arm adjusted in each aperture and having upon the end a crank-pin with curved block fitted to the cam-groove, the detachable bearing permitting the insertion of the block in the groove and the driving-disk then serving to oscillate the feed-shaft as required.

8. A crank-placer or analogous tool having a rotating driving-shaft and a feed-screw with oscillating lever to actuate the same, the combination, with each part, of a disk having cam-groove in its face, said groove being partly concentric and partly with a flat curve connected abruptly to the ends of the concentric portion, a bearing projected at right angles to the disk, a feed-shaft fitted to the bearing and provided with feed-crank and crank-pin upon its outer end connected with the oscillating lever and the shaft having upon its inner end an arm with crank-pin having block fitted to the cam-groove, and the block provided upon its inner side with a notch to pass the two angles or corners of the groove, substantially as herein set forth.

9. In a crank-placer or shaping-machine having a cross-head with movable table to support the work and feed-screw to actuate each table with ratchet-gearing upon the feed-screw to rotate the same, the combination, with a reciprocating ram and pitman pivoted thereto, of a bearing with plate at one side of each pitman, a bearing in each plate with driving-disk journaled therein, and an eccentric crank-plate fitted to the face of each disk with crank-pin connected to the pitman as set forth, a cam-groove in the driving-disk on the side next to the frame-plate, an aperture in the frame-plate for a feed-crank adjacent to each groove, a bearing fitted detachably to the frame-plate over each aperture, the feed-shaft in each bearing with arm having a roll or block fitted to the cam-groove, and the feed-shaft having an adjustable crank-pin with connec-

tion to the ratchet-gearing upon the cross-head, the whole arranged and operated substantially as herein set forth.

10. In a crank-placer or analogous tool having a main frame with cross-head or table adjustable vertically thereon, a feed-screw upon each cross-head or table, ratchet-gearing upon the cross-head or table to turn the feed-screw, an oscillating lever to actuate each ratchet-gearing with steps to regulate its movement, a feed-shaft upon the frame with a crank-pin to actuate the ratchet-gearing, a link connecting the crank-pin with the oscillating lever, and a friction sliding joint interposed between the feed-shaft and feed-screw, whereby the steps automatically vary the operation of the link upon the oscillating lever when the table is raised or lowered upon the frame.

11. In a crank-placer or analogous tool having a main frame with cross-head or table adjustable vertically thereon, and a feed-shaft having means for oscillating the same, and a crank-pin to actuate the feed-screw, the combination, with each part, of ratchet-gearing to drive each feed-screw, a vibrating stud connected with each ratchet-gearing, steps to limit the opposite movements of each stud, and a link connecting each stud with the feed-crank pin and having a friction sliding joint between its extremities whereby the steps automatically change the length of the link when the table is raised or lowered upon the frame, substantially as herein set forth.

12. In a crank-placer having a ram with means for reciprocating the same, and a cross-head adjustable vertically beneath the ram with table to support the work-piece, and a fixed bearing upon the frame in the rear of each cross-head with feed-shaft and crank as set forth, the combination, with the cross-head and each feed-shaft, of the feed-screw upon the cross-head, ratchet-gearing to drive each feed-screw, a vibrating stud upon an oscillating lever connected with each ratchet-gearing, steps upon the cross-head to limit the opposite movements of each stud, and a link connecting each stud with the feed-crank pin and having a friction sliding joint between its extremities, whereby the steps automatically change the length of the link when the cross-head is raised or lowered upon the frame.

13. In a crank-placer or shaping-machine having an extension-base and a cross-head above the same with table movable thereon, the combination, with each part, of a rail secured to the extension-base and having a rib extended from one edge of the rail over the upper surface of the table, and a leg or standard projected from the table and offset laterally to rest upon the rail beneath such rib.

14. In a crank-placer or shaping-machine, the combination, with the machine-frame having an extension-base upon the front corner of the same, with a cross-head adjustable vertically above such base, of a rail secured upon such base and provided with means for varying the height of its opposite ends, to set it level or parallel with the cross-head, a table movable upon the cross-head, and a leg fitted to the top of the rail and vertically movable upon the table to compensate for the height of the table above the rail.

15. In a crank-placer or shaping-machine, the combination, with the machine-frame having an extension-base upon the front corner of the same with a cross-head adjustable vertically above such base, of a rail secured upon such base and provided with means for varying the height of its opposite ends to set it level, a table movable upon the cross-head, an adjustable leg fitted to vertical guides upon the table and having a level foot upon its lower end adapted as a gage for setting the rail, substantially as herein set forth.

16. In a crank-placer or shaping-machine, the combination, with the machine-frame having an extension-base upon the front corner of the same with a cross-head adjustable vertically above such base, of a rail secured upon such base and provided with means for varying the height of its opposite ends, a rectangular box-table movable upon the cross-head with a recess in its front side and vertical guides within such recess, a leg adjustable within such guides and provided with means for clamping it when adjusted, and such leg having a level foot at the bottom for setting the rail, substantially as herein set forth.

17. In a crank-placer or shaping-machine, the combination, with the machine-frame having an extension-base upon the front corner of the same with the cross-head adjustable vertically above such base, of a rail secured upon such base and provided with means for varying the height of its opposite ends, a rectangular box-table movable upon the cross-head and projected beyond the front edge of the base, a rail secured removably upon the front edge of the base and provided with means for varying the height of its opposite ends as set forth, the table having a recess in the front with vertical guides over the said rail, and having the leg fitted adjustably to such guides to rest upon the rail, substantially as herein set forth.

18. In a crank-placer or shaping-machine, the combination, with the machine-frame having an extension-base upon the front corner of the same with the cross-head adjustable vertically above such base, of a rail secured upon such base and provided with means for varying the height

of its opposite ends, a rectangular box-table movable upon the cross-head and projected beyond the front edge of the base, the base having slots in its upper surface and a rail secured detachably upon the front edge of the base by bolts fitted to such slots, and the box having a recess in the front with a leg secured therein and adjustable vertically to rest upon the rail, substantially as herein set forth.

19. In a crank-placer or shaping-machine, the combination, with the machine-frame having an extension-base upon the front corner of the same, with a cross-head adjustable vertically above such base, of a table upon the cross-head with leg vertically movable upon the same, a rail secured upon the bed to support such leg and provided with means for pressing it upwardly against the under side of the leg to prevent the vibration of the table, substantially as herein set forth.

20. In a crank-placer or shaping-machine having an extension-base and a cross-head above the same with table movable thereon, the combination, with such parts, of a rail-bed secured to the extension-base, a rail attached to such bed, a screw for setting such rail parallel with the cross-head, and a leg upon the table to contact with the rail and vertically adjustable to compensate for the elevation of the cross-head, substantially as herein set forth.

21. In a crank-placer or shaping-machine having an extension-base and a cross-head above the same with table movable thereon, the combination, with such parts, of a rail-bed secured to the extension-base, a rail attached to such bed, a leg upon the table with means for adjusting it vertically to contact with the rail in various locations of the cross-head, and vertical screws for raising the rail upon its bed to assist in such compensation, and operating also to set the rail parallel with the cross-head and to press the rail against the bottom of the leg to prevent the vibration of the table.

22. In a crank-placer or shaping-machine having an extension-base and a cross-head above the same with table movable thereon, the combination, with such parts, of a rail-bed secured to the extension-base, and having vertical guides as set forth, a rail fitted to such vertical guides and having ribs to clamp the same, the two screws fitted to the rail-bed and rail to vary the height of its opposite ends, as and for the purpose set forth.

23. In a crank-placer or shaping-machine, the combination, with a shaping-machine having an extension-base and a cross-head above the same with table movable thereon, of a leg projected from the table and a rail supported upon the base to sustain such leg, the rail having a seat to support the leg, and a rib elevated above such seat to protect the same from abrasion.

24. In a crank-placer or shaping-machine, the combination, with a shaping-machine having an extension-base and a cross-head above the same with table movable thereon, of a leg projected from the table and a rail supported upon the base to sustain such leg, the rail having a seat to support the leg, a rib fitted above such seat to form a foot-rest, and a gutter between such rib and seat to receive dirt and grit as and for the purpose set forth.

25. In a crank-placer or shaping-machine, the combination, with the machine-frame having an extension-base at the front, with a cross-head adjustable vertically above such base, and table movable horizontally upon such cross-head, of a rail secured upon such base and provided with means for positively varying the height of its opposite ends to set it level or parallel with the cross-head, and a projection from the table to rest upon such rail.

700,680. AUTOMATIC BELT-SHIFTER. HOMER L. FANCHER, Baldwinville, N. Y., assignor to the Fancher Machine Company, Baldwinville, N. Y., a Corporation of New York. Filed Mar. 27, 1901. Serial No. 22,121. (No model.)

Claim.—1. The combination with a pivotally-mounted body, of an oscillatory frame mounted upon one end of the body, fast and loose pulleys mounted on said frame, a belt for driving said pulleys, a swing-frame mounted upon the other end of the body and means actuated by the swing-frame for oscillating the other frame and thereby shifting the belt from one pulley to the other.

2. The combination with a pivotally-mounted body, of an oscillatory frame mounted upon one end of the body, fast and loose pulleys

mounted on said frame, a belt for driving said pulleys, an additional pulley mounted on the frame and actuated by the fast pulley, a second belt driven by said additional pulley, a swing-frame mounted upon the other end of the body, an idler carried by the swing-frame and arranged to engage the additional belt whereby said additional belt is tensioned by the movement of the swing-frame for oscillating the former frame and thereby shifting the driving-belt from the loose to the tight pulley.

3. The combination with a pivotally-mounted body provided with a slot, of a swing-frame having a movable bearing in said slot, idlers in said frame, a shoulder on said body engaged by the frame as said frame is swung for moving the bearings in said slot and thereby shifting the position of the idlers and a belt engaged by said idlers.

4. The combination with a pivotally-mounted body provided with a slot, of a swing-frame having a movable bearing in said slot, idlers in said frame, a shoulder on said body engaged by the frame as said frame is swung for moving the bearings in said slot and thereby shifting the position of the idlers, an oscillatory frame mounted on the body, fast and loose pulleys mounted on the frame, a belt for driving said pulleys, an additional pulley mounted on the oscillatory frame and driven by the fast pulley, and a second belt driven by the additional pulley and engaged with said idlers, whereby the change in position of the swing-frame rocks the oscillatory frame and thereby shifts the driving-belt from one pulley to the other.

5. The combination with a vertical rotatable shaft having a pulley, of a body pivoted on the shaft, an oscillatory frame upon one end of said body, a shaft journaled on the frame, fast and loose pulleys on the shaft, a driving-belt driven from the former pulley for driving the fast and loose pulleys, an additional pulley mounted upon the second shaft, a swing-frame upon the other end of the body, idlers mounted on the swing-frame, a belt driven from the additional pulley and engaged with said idlers whereby as the swing-frame is moved the idlers act upon the driven belt to rock the oscillating frame for automatically shifting the driving-belt from one pulley to the other.

6. The combination with a suitable support, an oscillatory frame carrying fast and loose pulleys and a driven pulley, of a swing-frame, an additional pulley carried by the swing-frame, a belt for transmitting power from the driven pulley to the latter pulley, a driving-belt for the fast and loose pulleys and means provided on the swing-frame and acting upon the driven belt whereby the movement of the swing-frame rocks the oscillating frame and shifts the driving-belt from the fast to the loose pulley and vice versa.

7. The combination with a support having oppositely-arranged bearings, of an oscillatory frame pivoted between said bearings, a shaft journaled on the frame and provided with tight and loose pulleys, a belt for driving said pulleys and means for rocking the oscillating frame and thereby shifting the driving-belt from one pulley to the other.

700,681. COMBINED DOOR KNOBS AND HELL. JOHN W. FERRIS, DENVER, Colo., assignor of one-half to MISS R. A. HAYNES, DENVER, Colo. Filed Dec. 9, 1900. Serial No. 55,245. (No model.)

Claim.—1. In a device of the class described, the combination of an inner knob composed of inner and outer sections, a bracket connect-

ing the sections, a reciprocating spring-actuated rod provided with an opening, and a resilient bell-crank lever (subdivided on the bracket and provided at one arm with a head, the other arm of the bell-crank lever being extended through the opening of the reciprocating rod and arranged to engage the latter when the rod is moved inward, whereby the swing of the bell-hammer is limited, the rod-engaging arm of the bell-crank lever being also arranged to engage the bracket to limit the movement of the bell-crank lever when the rod is moved outward, substantially as described.

2. A device of the class described comprising an inner knob having a bell, a bracket mounted within the inner knob, a reciprocating rod adapted to be pushed inward, a coiled spring connected with the rod and with the bracket and adapted to throw the former outward, a pivot or stud mounted on the bracket, and a resilient bell-crank lever provided at its angle with a coil arranged on the pivot or stud, said bell-crank lever being provided at one arm with a head and having its other arm connected with the rod and arranged to engage the latter to limit the movement of the rod and the bell-hammer, substantially as described.

3. A device of the class described comprising an inner knob having a bell, a reciprocating rod adapted to be pushed inward and provided with an aperture, a spring for throwing the rod outward, and a resilient bell-crank lever provided at one arm with a head, the other arm of the bell-crank lever being approximately L-shaped and operating in the aperture of the rod and arranged to engage and limit the movement of the latter, substantially as described.

700,682. LUBRICANT-INDICATOR. PAUL C. R. GOSCH, Hamburg, Germany, assignor of one-half to FIRM OF FRANK SANDER, Hamburg, Germany. Filed July 26, 1901. Serial No. 60,724. (No model.)

Claim.—1. Apparatus such as described, comprising a tube connectible with the steam-space of a power-cylinder, a needle at the free end of said tube, and means for moving a record-card across the needle in front of the same, for the purpose set forth.

2. Apparatus such as described, comprising a tube connectible with the steam-space of a power-cylinder, a needle at the free end of said tube, the latter provided with a pressure-gauge, a thermometer, and with a stop-cock on the needle side of said device, and means for moving a record-card across the needle in front of the same, for the purpose set forth.

3. Apparatus such as described, comprising a tube connectible with the steam-space of a power-cylinder, a needle at the free end of said tube, the latter provided with a pressure-gauge, a thermometer, and with a stop-cock on the needle side of said device and means for moving a record-card across the needle in front of the same, for the purpose set forth.

4. Apparatus such as described, comprising a tube connectible to a steam-cylinder, a needle at the free end of said tube and a record-card carrier adapted to oscillate in front of said needle, whereby the card will be moved across the jet of steam to have a permanent oil-record on the card to indicate the distribution and quality of the oil in the cylinder, for the purpose set forth.

5. Apparatus such as described, comprising a tube having a steam

connection at one end, a needle and a stop-cock controlling it at the other end, a thermometer and a pressure-gauge intermediate the ends, and an indicator-drum to carry a record-card adapted to be oscillated in front of said needle, for the purpose set forth.

700,683. METHOD OF TESTING LUBRICANTS. PAUL C. R. GOSCH, Hamburg, Germany, assignor of one-half to FIRM OF FRANK SANDER, Hamburg, Germany. Original application filed July 26, 1901. Serial No. 60,724. Divided and this application filed Oct. 21, 1901. Serial No. 70,452. (No model.)

Claim.—1. The herein-described method, which consists in causing a jet of fluid from the power-cylinder of a motive-fluid-operated engine to impinge upon a surface moving across said jet and capable of indicating the relative quantity of lubricant mixed with the steam of said jet, substantially as and for the purpose set forth.

2. The herein-described method, which consists in causing a jet of fluid from the power-cylinder of a motive-fluid-operated engine to impinge upon a surface moving across said jet in synchronism with the movements of the engine-piston and capable of indicating the relative quantity of lubricant in said jet, substantially as and for the purpose set forth.

3. The herein-described method, which consists in causing a jet of fluid from the power-cylinder of a fluid-operated engine to impinge upon a surface capable of visibly indicating and recording the lubricant therein and moving across said jet, and simultaneously indicating the pressure under which the jet is produced, substantially as and for the purpose set forth.

4. The herein-described method, which consists in causing a jet of fluid from the power-cylinder of a motive-fluid-operated engine to impinge upon a surface oscillating in front of the jet in synchronism with the reciprocations of the engine-piston, said surface capable of visibly indicating and recording the lubricant forced thereon, substantially as and for the purpose set forth.

700,684. PHOTOGRAPHIC ROLL-FILM. ROBERT KAMMIGER, Berlin, Germany, assignor to Action Gesellschaft für Aufn. Photographie, Berlin, Germany. Filed Feb. 28, 1900. Renewed Mar. 19, 1900. Serial No. 59,002. (No specimens.)

Claim.—Photographic roll-film having a coating, impermeable to water, on the wrapper or covering, which comes into direct contact with the emulsion film.

700,685. WINDING IMPLEMENT. HARRY HAYVILL, Los Angeles, Cal. Filed Aug. 14, 1891. Serial No. 72,005. (No model.)

Claim.—1. A winding implement comprising a twisted blade centrally and rigidly mounted in the front end of a handle and having its longitudinal center line coincident with the longitudinal center line of the handle, and a handle having a globular enlargement on the front and thereof extending equally in all directions in a line at right angles from the longitudinal center line of the handle, said enlargement forming a fulcrum whereby a cord in the blade may be pried out of the ground.

2. In a winding implement, a handle thereof having a globular enlarged front end, said enlargement extending equally around the longitudinal center line of the handle and a portion extending rearwardly from said enlarged portion, adapted to be grasped by the hand, in combination with a blade therefor centrally and rigidly mounted in the front end of the handle with its longitudinal center line coincident with the longitudinal center line of the handle.

700,686. VEHICLE-WHEEL. DANIEL H. HAYWOOD, New York, N. Y., assignor to the Wheel Within Wheel Company, New York, N. Y., a Corporation of New Jersey. Filed Mar. 1, 1898. Serial No. 94,505. (No model.)

Claim.—1. In a wheel, the combination with a hub, spokes and a rim, of a channel tire-rim having outwardly-flaring flanges, a tire supported by said channel tire-rim, an annular cushioning device between the tire-rim and the first said rim, a floating plate, spokes arranged on either side of the said annular cushioning device, and connecting the said floating plate and the tire-rim together, said spokes having portions which engage the sides of the outwardly-flaring flanges of the tire-rim; and an intermediate guide-plate between the floating plate and the hub.

2. In a wheel, the combination with a hub, spokes and a rim, of a channel tire-rim having outwardly-flaring flanges, a tire supported by said channel tire-rim, an annular cushioning device between the tire-rim and the first said rim, a floating plate, spokes arranged on either side of the said annular cushioning device, and connecting the said floating plate and the tire-rim together, said spokes having portions which engage the sides of the outwardly-flaring flanges of the tire-rim, the outside of which portions are substantially flush with the extreme outside edges of the said outwardly-flaring flanges; and an intermediate guide-plate between the floating plate and the hub.

3. In a wheel, the combination with a hub, spokes and a rim, of a channel tire-rim having outwardly-flaring flanges, a tire supported by said channel tire-rim, an annular cushioning device between the tire-rim and the first said rim, a floating plate, spokes arranged on either side of the said annular cushioning device, and connecting the said floating plate and the tire-rim together, said spokes having portions which engage the sides of the outwardly-flaring flanges of the tire-rim, bolts passing through the said spokes, the channel tire-rim and the tire; and an intermediate guide-plate between the floating plate and the hub.

4. In a wheel, the combination with a hub, spokes and a rim, of a channel tire-rim having outwardly-flaring flanges, a tire supported by said channel tire-rim, an annular cushioning device between the tire-rim and the first said rim, a floating plate, spokes arranged on either side of the said annular cushioning device and connecting the said floating plate and the tire-rim together, said spokes having portions which engage the sides of the outwardly-flaring flanges of the tire-rim, the outside of which portions are substantially flush with the extreme outside edges of the said outwardly-flaring flanges, bolts passing through the said spokes, the channel tire-rim and the tire; and an intermediate guide-plate between the floating plate and the hub.

5. In a wheel, the combination with a hub, spokes and a rim, of a channel tire-rim having outwardly-flaring flanges, and adapted to support a tire, an annular cushioning device between the tire-rim and the first

said rim, a floating plate, spokes comprising each two members secured together and arranged upon opposite sides of the said annular cushioning device, said spokes secured at their inner ends to the floating plate and at their outer ends engaging the inner face of the channel tire-rim and also engaging the sides of the outwardly-flaring flanges thereof; and an intermediate guide-plate between the floating plate and the hub.

6. In a wheel, the combination with a hub, spokes and a rim, of a channel tire-rim having outwardly-flaring flanges, and adapted to support a tire, an annular cushioning device between the tire-rim and the first said rim, a floating plate, spokes comprising each two members secured together and arranged upon opposite sides of the said annular cushioning device, said spokes secured at their inner ends to the floating plate and at their outer ends engaging the inner face of the channel tire-rim and also engaging the sides of the outwardly-flaring flanges thereof, bolts passing through the said spokes, the channel tire-rim and the tire; and an intermediate guide-plate between the floating plate and the hub.

7. In a wheel, the combination with a hub, spokes and a rim, of a channel tire-rim adapted to support a tire, said channel tire-rim having outwardly-flaring separable flanges, an annular cushioning device between the tire-rim and the first said rim, a floating plate, spokes comprising each two members secured together and arranged upon opposite sides of the said annular cushioning device, said spokes secured at their inner ends to the floating plate and at their outer ends engaging the inner face of the channel tire-rim and also engaging the sides of the outwardly-flaring flanges thereof; and an intermediate guide-plate between the floating plate and the hub.

8. In a wheel, the combination with a hub, spokes and a rim, of a channel tire-rim adapted to support a tire, said channel tire-rim having outwardly-flaring separable flanges, an annular cushioning device between the tire-rim and the first said rim, a floating plate, spokes comprising each two members secured together and arranged upon opposite sides of the said annular cushioning device, said spokes secured at their inner ends to the floating plate and at their outer ends engaging the inner face of the channel tire-rim and also engaging the sides of the outwardly-flaring flanges thereof, bolts passing through the said spokes, the channel tire-rim and the tire; and an intermediate guide-plate between the floating plate and the hub.

9. In a wheel, the combination with a hub, spokes and a rim, of a channel tire-rim adapted to support a tire, said channel tire-rim having outwardly-flaring separable flanges, an annular cushioning device between the tire-rim and the first said rim, a floating plate, spokes comprising each two members secured together and arranged upon opposite sides of the said annular cushioning device, said spokes secured at their inner ends to the floating plate and at their outer ends engaging the inner face of the channel tire-rim and also engaging the sides of the outwardly-flaring flanges thereof, the outside faces of said spokes being substantially flush with the extreme outside edges of the said outwardly-flaring flanges, their bolts passing through the said spokes, the channel tire-rim and the tire, flush with the said bolts, recessed into said spokes; and an intermediate guide-plate between the floating plate and the hub.

10. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the hub member comprising two hub-sections, spokes and a rim, the said hub-sections having grooves therein, the grooves in one section being at right angles to the grooves in the opposite section, the said tire member including a floating plate having grooves at right angles therein; together with two intermediate guide-plates, each comprising an annular disk having projecting tongues thereon, arranged at right angles to each other upon opposite sides thereof, the said guide-plates disposed between the floating plate and the hub-sections, with the tongues thereof engaging the grooves in the said floating plate and hub-sections.

11. A wheel comprising two relatively movable members, one a tire member and the other a hub member, and having a cushioning device between them, the hub member comprising two hub-sections, spokes and a rim, the said hub-sections having a plurality of parallel grooves therein, the grooves in one section being at right angles to the grooves in the opposite section, the said tire member including a floating plate having a plurality of parallel grooves at right angles therein; together with two intermediate guide-plates, each comprising an annular disk having two sets of parallel projecting tongues thereon, the sets arranged at right angles to each other upon opposite sides thereof, the said guide-plates disposed between the floating plate and the hub-sections, with the tongues thereof engaging the grooves in the said floating plate and hub-sections.

700,687. WRITING-MACHINE. EDWARD R. RICE, Brooklyn, N. Y., assignor to Mechanical Improvements Company, New York, N. Y., a Corporation of New York. Filed Apr. 24, 1891. Serial No. 67,562. (No model.)

Claim.—1. In a writing-machine, the combination of a platen, a

segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections hinged at their rear ends to the type-bars and at their front ends hinged to the frame in lines lying in different transverse vertical planes, the flaring connections being divided into series of unequal lengths and means acting upon the flaring connections intermediate their ends for flexing them to pull the type-bars to the printing-point with an increasing velocity.

2. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections connected at their rear ends to the type-bars by universal joints and at their front ends hinged to the frame in lines lying in different transverse vertical planes, the flaring connections being divided into series of unequal lengths and means acting upon the flaring connections intermediate their ends for flexing them to pull the type-bars to the printing-point with an increasing velocity.

3. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections each composed of two links arranged end to end and united by a universal joint and connected at their rear ends to the type-bars by universal joints and at their front ends hinged to the frame in lines lying in different transverse vertical planes, the flaring connections being divided into series of unequal lengths, and means acting upon the flaring connections intermediate their ends for flexing them to pull the type-bars to the printing-point with an increasing velocity.

4. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections each composed of two links arranged end to end and united by a universal joint and connected at their rear ends to the type-bars by universal joints and at their front ends hinged to the frame in lines lying in different transverse vertical planes, the flaring connections being divided into series of unequal lengths, and means acting upon the flaring connections intermediate their ends for flexing them to pull the type-bars to the printing-point with an increasing velocity.

5. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections each composed of two links united by a universal joint and hinged at its rear end to its type-bar and at its front end to a fixed plate or part of the frame and extending in a substantially straight line from the type-bar to its point of connection to the frame and means acting from above the flaring connections to flex them and pull the type-bars to the printing-point with an increasing velocity, the straight-line arrangement of the flaring connections offering the least resistance obtainable at the commencement of their flexure.

6. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections hinged at their rear ends to the type-bars and at their front ends

hinged to the frame in lines lying in different transverse vertical planes, the flaring connections being divided into series of unequal lengths, finger-pieces arranged in transverse rows above the flaring connections and connections between the finger-pieces and the flaring connections intermediate the ends of the latter to flex them downwardly on the depression of the finger-pieces and thereby pull the type-bars to the printing-point with an increasing velocity.

7. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections each composed of two links arranged end to end and united by a universal joint and hinged at their rear ends to the type-bars and at their front ends hinged to the frame in lines lying in different transverse vertical planes, the flaring connections being divided into series of unequal lengths, finger-pieces arranged in transverse rows above the flaring connections and connections between the finger-pieces and the flaring connections intermediate the ends of the latter to flex them downwardly on the depression of the finger-pieces and thereby pull the type-bars to the printing-point with an increasing velocity.

8. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections each composed of two links arranged end to end and united by a universal joint and connected at their rear ends to the type-bars by universal joints and at their front ends hinged to the frame in lines lying in different transverse vertical planes, the flaring connections being divided into series of unequal lengths, finger-pieces arranged in transverse rows above the flaring connections and connections between the finger-pieces and the flaring connections intermediate the ends of the latter to flex them downwardly on the depression of the finger-pieces and thereby pull the type-bars to the printing-point with an increasing velocity.

9. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections each composed of two links arranged end to end and united by a universal joint and connected at their rear ends to the type-bars by universal joints and at their front ends hinged to the frame in lines lying in different transverse vertical planes, the flaring connections being divided into series of unequal lengths, finger-pieces arranged in transverse rows above the flaring connections and connections between the finger-pieces and the flaring connections intermediate the ends of the latter to flex them downwardly on the depression of the finger-pieces and thereby pull the type-bars to the printing-point with an increasing velocity.

10. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections each composed of two links arranged end to end and united by a universal joint and connected at their rear ends to the type-bars by universal joints and at their front ends hinged to the frame in lines lying in different transverse vertical planes, the flaring connections being divided into series of unequal lengths, finger-pieces arranged in transverse rows above the flaring connections and connections between the finger-pieces and the flaring connections intermediate the ends of the latter to flex them downwardly on the depression of the finger-pieces and thereby pull the type-bars to the printing-point with an increasing velocity.

11. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections each hinged at its rear end to its type-bar and at its front end to a fixed plate or part of the frame and extending in a substantially straight line from the type-bar to its point of connection to the frame and means acting from above the flaring connections to flex them and pull the type-bars to the printing-point with an increasing velocity, the straight-line arrangement of the flaring connections offering the least resistance obtainable at the commencement of their flexure.

12. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections each composed of two links united by a universal joint and hinged at its rear end to its type-bar and at its front end to a fixed plate or part of the frame and extending in a substantially straight line from the type-bar to its point of connection to the frame and means acting from above the flaring connections to flex them and pull the type-bars to the printing-point with an increasing velocity, the straight-line arrangement of the flaring connections offering the least resistance obtainable at the commencement of their flexure.

13. In a writing-machine, the combination of a platen, a segmental type-bar support arranged in a plane below the platen, type-bars pivoted thereto and normally lying toward the front of the machine, flaring connections each connected by a universal joint at its rear end to its type-

type-bar to the printing-point with an increasing velocity, the straight-line arrangement of the flexing connections offering the least resistance obtainable at the commencement of their flexure, and means for at will changing the relation of the plates and type-bar support.

43. In a writing-machine, the combination of a plate, a segmental type-bar support arranged in a plane below the plate, type-bars pivoted therein and normally lying toward the front of the machine, a series of links of substantially equal length pivoted in different transverse lines at or near the front of the machine, a series of links hinged to the rear ends of the first-named links and operatively connected at their rear ends to the type-bars, finger-plates, devices which, on the depression of the finger-plates act upon the flexing connections intermediate the ends to flex the corresponding pairs of links and pull the type-bars to the printing-point with an increasing velocity, and means for at will changing the relation of the plate and type-bar support.

44. In a writing-machine, the combination of a plate, a segmental type-bar support arranged in a plane below the plate, type-bars pivoted therein and normally lying toward the front of the machine, flexing connections extending from front to rear of machine under the type-bars and connected at their rear ends to the type-bars and each connected at its front end to a fixed plate or part of the frame, finger-plates arranged in transverse rows in front of the type-bars and above the flexing connections, and vertically-movable connections between the finger-plates and flexing connections, whereby, on the depression of a finger-plate the corresponding flexing connection is forced downwardly and the type-bar pulled to the printing-point with an increasing velocity.

45. In a writing-machine, the combination of a plate, a segmental type-bar support arranged in a plane below the plate, type-bars pivoted therein and normally toward the front of the machine, flexing connections, each composed of two links hinged together, extending from front to rear of the machine under the type-bars and connected at their rear ends to the type-bars and each connected at its front end to a fixed plate or part of the frame, finger-plates arranged in transverse rows in front of the type-bars and above the flexing connections, and vertically-movable connections between the finger-plates and flexing connections, whereby, on the depression of a finger-plate, the corresponding flexing connection is forced downwardly and the type-bar pulled to the printing-point with an increasing velocity.

46. In a writing-machine, the combination of a vertically-movable finger-plate, a link lying below it and substantially in a plane at right angles to the line of movement of the finger-plate and having one end connected to a fixed part of the frame, a second link operatively connected to the part to be extended and united with the free end of the first-named link by a hinge-joint, and means directly interposed between the finger-plate and the first-named link to depress the latter and thereby cause the second-named link to approach said fixed part of the frame.

47. In a writing-machine, the combination of a vertically-movable finger-plate, a link lying below it and substantially in a plane at right angles to the line of movement of the finger-plate and having its front end connected to a fixed part of the frame, a second link operatively connected at one end to the part to be extended and at the other end united by a hinge-joint, to the rear end of the first-named link, and a device interposed between the finger-plate and the hinge-joint acting the two links to depress said joint and thereby cause the second-named link to approach said fixed part.

48. The combination of a pivotal type-bar, its actuating connection consisting of two links united at their adjacent ends by a hinge-joint and arranged substantially in a plane at right angles to the line of movement of the type-bar, the rear end of one link being operatively connected with the type-bar and the front end of the other link with a fixed part of the frame, and the links being so disposed that the hinge-joint is in a plane slightly below the plane in which the two links lie, a push-pin finger-plate arranged above the said actuating connection and a device actuated by the finger-plate to further depress said hinge-joint and thereby throw the type-bar to the printing-point with a minimum initial resistance and an increasing resistance and velocity.

49. The combination of a plate, a type-bar segment mounted at right angles to the horizontal plane of the machine, type-bars mounted therein, connections for operating the type-bars having their rear ends arranged in an arc corresponding substantially to the curve of the segment and their front ends connected in similar transverse rows, finger-plates arranged above each connection and means for using open said connections intermediate their ends when the finger-plates are depressed to actuate the type-bars.

50. The combination of a plate, a type-bar segment mounted at an angle to the horizontal plane of the machine, type-bars mounted therein, connections of unequal length for operating the type-bars having their rear ends arranged in an arc corresponding substantially to the curve of the segment and their front ends mounted in similar transverse rows at different distances from the plate, finger-plates arranged above each con-

nection and means for using open said connections intermediate their ends when the finger-plates are depressed to actuate the type-bars.

51. The combination of a plate, a type-bar segment mounted at an angle to the horizontal plane of the machine, type-bars mounted therein, flexing connections of unequal length for operating the type-bars having their rear ends operatively connected directly to the type-bars in a curve corresponding with the curve of the segment and their front ends each connected to a fixed plate or part of the frame and arranged in similar transverse rows, and means for flexing each connection to operate the type-bars, said connections being respectively so arranged that when flexed their rear ends are caused to approach each fixed point.

52. The combination of a plate, a type-bar support, type-bars pivoted therein in a curve whose radial plane is at an angle to the horizontal plane of the machine, a series of independent fixed parts or plates attached to the frame near the front of the machine and arranged in transverse rows at different distances from the plate, flexing type-bar-operating connections of unequal length extending between each fixed plate and the type-bars, and means for using on each flexing connection intermediate their ends, to thereby cause their rear ends to approach said fixed points.

53. The combination of a plate, a type-bar support, type-bars pivoted therein in a curve whose radial plane is at an angle to the horizontal plane of the machine, a series of fixed parts or plates arranged in rows in similar segmental curves and at different distances from the plate, flexing type-bar-operating connections operatively connected with the type-bars at their rear ends and at their front ends to each fixed plate and consisting of jointed links, and means for flexing each connection to actuate the type-bars, said connections being so disposed that when flexed their rear ends approach each fixed point.

54. The combination of a plate, a type-bar support, type-bars pivoted therein in a curve whose radial plane is at an angle to the horizontal plane of the machine, a series of fixed parts or plates arranged in rows in similar segmental curves and at different distances from the plate, flexing type-bar-operating connections operatively connected with the type-bars at their rear ends and at their front ends to each fixed plate and consisting of jointed links, finger-plates arranged above said flexing connections, and devices of different lengths interposed between the finger-plates and said flexing connections intermediate their ends, the connections being so disposed that when flexed their rear ends approach each fixed point.

55. The combination of a plate, a type-bar support, type-bars pivoted therein in a curve whose radial plane is at an angle to the horizontal plane of the machine, flexing type-bar-operating connections composed of links arranged end to end and united by a hinge-joint and operatively connected at their rear ends to the type-bars and at their front ends to fixed parts of the frame arranged in similar curves transverse to the machine at different distances from the plate, each flexing connection converging from front to rear, a series of finger-plates arranged over each connection and means controlled by the finger-plates for flexing the connections, the latter being so disposed that when flexed their rear ends approach their front ends.

56. The combination of a plate, a segmental type-bar support, arranged below the plate with its concave face upward, type-bars pivoted therein, flexing type-bar-operating connections operatively connected with the type-bars at their rear ends and extending to the front of the machine in divergent lines and in similar concave or trough-like formation and there connected to fixed parts of the frame, finger-plates arranged above each connection in horizontal lines at different heights, and means on the depression of the finger-plates operating on each connection intermediate their ends to actuate the type-bars.

57. In a writing-machine, the combination of a plate, a segmental type-bar support arranged in a plane below the plate, a type-bar pivoted therein and normally lying toward the front of the machine, a flexing connection operatively connected at its rear end to the type-bar and extending toward the front of the machine and there connected to rest about a fixed part of the frame, a finger-plate arranged in front of the type-bar and over the flexing connection, and a connection between the finger-plate and the flexing connection, intermediate the ends of the latter, whereby it is flexed, on the depression of the finger-plate, to throw the type-bar to the printing-point with an increasing velocity.

700,888. **WHEATLEY, JR.** EDWARD E. HARR, BROOKLYN, and JAMES M. SWEETMAN, YONKERS, N. Y., assignors to Mechanical Improvements Company, New York, N. Y., a Corporation of New York. Filed Oct. 12, 1901. Serial No. 73,000. (No model.)

Claim.—1. The combination of a clock-movement and a printing-wheel mounted on the minute-arter of the clock-movement and comprising a rigid hub and a rigid rim elastically connected to the hub.

2. The combination of a clock-movement, and a marking-rim elastically mounted on the minute-arter of the clock-movement.

3. The combination of a clock-movement, a hub secured to the minute-arter thereof, a series of springs secured at their inner ends to the hub, and a rigid marking-rim secured to the outer ends of the springs.

4. The combination of a clock-movement, a printing-wheel fixed to the minute-arter thereof and comprising a rigid hub, a rigid marking-rim and elastic connections between the two, and a plate and an abutment arranged respectively on opposite sides of said rim.

5. In a time-stamp, the combination of a plate, a clock-movement, a clock-rotated shaft, a printing-wheel having a hub rigidly attached to said shaft and a printing-connection cooperating with said plate and means which afford a movement of the rim of said wheel independently of its hub and shaft.

6. In a time-stamp, the combination of a plate, a printing-wheel cooperating therewith, a clock-movement including a shaft upon which the hub of said wheel is rigidly mounted, and means which afford a movement of the printing-connection of said wheel independently of said shaft.

7. In a time-stamp, the combination of a plate, a printing-wheel cooperating therewith, a clock-movement including a shaft which carries said wheel, and means which afford a movement of the printing-connection of said wheel radially or toward and from said shaft.

8. In a time-stamp, the combination of a plate, a printing-wheel cooperating therewith, a clock-movement including a shaft upon which said wheel is mounted and adapted to turn for a limited distance, means which afford a movement of the rim of said wheel radially or toward and from said shaft, and means for limiting the radial movement of said rim.

9. In a time-stamp, the combination of a plate, a printing-wheel cooperating therewith, a clock-movement including a shaft upon which said wheel is directly mounted to turn therewith in order to expose different printing-surfaces on the wheel, and spring-supporting means which afford a movement of the printing-connection of said wheel toward and also radially or toward and from said shaft.

10. In a time-stamp, the combination of a clock-movement, a right arbor operated by said clock-movement, a printing-wheel mounted upon said arbor to rotate therewith and to turn thereon, means which afford a movement of said wheel radially or toward and from the arbor, and a plate which cooperates with the printing-wheel, whereby the force of the impact between the plate and printing-wheel will not be transmitted to the arbor.

11. In a time-stamp, the combination of a clock-movement, an arbor operated by said clock-movement, a printing-wheel, a radially-acting spring connection between the rim of said wheel and the arbor, and a plate which cooperates with the printing-wheel, whereby the force of the impact between the plate and printing-wheel will not be transmitted to the arbor, and the arbor is capable of rotating a limited distance independently of the said rim.

12. In a time-stamp, the combination of a clock-movement, an arbor operated by said clock-movement, a printing-wheel surrounding said arbor and having springs interposed between its printing-rim and its hub, a plate cooperating with the printing-wheel, and means for limiting the movement of the printing-rim independently of the arbor.

13. In a time-stamp, the combination of a clock-movement, an arbor operated by said clock-movement, a printing-wheel operatively connected to said arbor, said printing-wheel having a plurality of said springs interposed between its printing-rim and said arbor, a plate cooperating with the printing-wheel, and an abutment independent of the clock-movement and against which the rim of the printing-wheel is adapted to be forced by the plate.

14. In a time-stamp, the combination of a clock-movement, a right arbor operated by said clock-movement, a printing-wheel mounted directly on said arbor, means which afford a movement of said wheel in every direction independently of the arbor, a plate which cooperates with the printing-wheel, whereby the force of the impact between the plate and printing-wheel will not be transmitted to the arbor, and whereby the arbor may turn for a limited distance independently of the printing-connection of said wheel, and means for limiting the said independent movement of said printing-wheel in a direction transverse to said arbor.

15. In a time-stamp, the combination of a plate, a clock-movement, a right arbor operated by said clock-movement, a right printing-connection which is mounted concentrically on and is carried directly by said arbor, and means which permit the printing-connection to move for a limited distance in any direction independently of said arbor.

16. In a time-stamp, the combination of a plate, a clock-movement, a printing-connection which surrounds and is directly connected to the minute-arter of said clock-movement, and means for affording a movement in any direction of said printing-connection independently of the minute-arter for a limited distance, so that the shock due to the impact between the plate and printing-connection will not be transmitted to said arbor, and so that the arbor can rotate for a limited distance independently of said printing-connection.

17. In a time-stamp, the combination of a plate, a hand-operated plunger for said plate, a clock-movement, a minute-printing surface which surrounds and is directly connected to the minute-arter of said clock-movement, means for affording a transverse and rotary movement of said printing-connection independently of the minute-arter for a limited distance, so that the shock due to the impact between the plate and printing-connection will not be transmitted to said arbor, a second independently-operable hand-printing surface, and means operatively connected to said minute-arter for moving said last-mentioned printing-connection.

18. In a time-stamp, the combination of a plate, a clock-movement, a minute-printing surface which surrounds and is mounted concentrically upon the minute-arter of said clock-movement, springs which connect said printing-connection to said arbor to afford a movement of said printing-connection independently of the minute-arter for a limited distance in every direction so that the shock due to the impact between the plate and printing-connection will not be transmitted to said arbor, and so that the arbor may turn for a limited distance independently of said printing-connection, on hand-printing wheel and operative connections between the hand-printing wheel and the minute-arter for giving a partial rotation to the hand-wheel for each complete rotation of the minute-wheel.

19. In a time-stamp, the combination of a plate, a clock-movement, and minute and hour printing wheels which are connected to and supported by the minute-arter of said clock-movement and surround the same, each of said wheels comprising means for affording a movement of the printing-connection thereof independently of the minute-arter, so that the shock due to the impact between the plate and printing-connection of said wheels will not be transmitted to the minute-arter.

20. In a time-stamp, the combination of a plate, a clock-movement, minute and hour printing wheels which are connected to and supported by the minute-arter of said clock-movement, each of said wheels comprising means for affording a movement of the printing-connection thereof independently of the minute-arter, so that the shock due to the impact between the plate and the printing-connection of said wheels will not be transmitted to the minute-arter, and date-printing wheels supported independently of and disconnected from said minute and hour printing wheels.

21. In a time-stamp, the combination of a plate, a clock-movement, a printing-wheel which is operatively connected to the minute-arter of said clock-movement and which comprises means for affording a movement of the printing-connection of said wheel independently of the minute-arter for a limited distance so that the shock due to the impact between the plate and printing-connection will not be transmitted to said minute-arter, a day-printing wheel supported independently of said minute-wheel, and hand-operated means for rotating the day-printing wheel to change the day thereon.

22. In a time-stamp, the combination of a plate, a clock-movement, minute and hour printing wheels which are operatively connected to the minute-arter of said clock-movement and which comprise each means for affording a movement of the printing-connection of said wheel independently of the minute-arter for a limited distance so that shock due to the impact between the plate and printing-connection will not be transmitted to said minute-arter, day, month and year printing wheels supported independently of and disconnected from said minute and hour wheels, and hand-operated means for rotating the day, month and year printing wheels to change the position of the printing characters thereon to agree with those on the automatically-operated minute and hour wheels.

23. In a time-stamp, the combination of a clock-movement, a hub secured to the minute-arter thereof, a minute-marking rim elastically con-

needed to said hub, a sleeve surrounding said arbor, a hub mounted on said sleeve, and an hour-marking rim electrically connected to said sleeve-mounted hub, and means controlled by the minute-arbor for turning said hour-marking rim and hub one step for each complete rotation of the minute-marking rim and hub.

24. In a time-stamp, the combination of a clock-movement, time-wheel actuated thereby, dating-wheel, vertically-sliding key-stem, and wheel-actuating device interposed between the respective dating-wheel and stem and a platen for obtaining an impression from all of said wheels.

25. In a time-stamp, the combination of a clock-movement, time-wheel actuated thereby, independently-mounted dating-wheel arranged in alignment with said time-wheel, vertically-sliding key-stem, and wheel-actuating device interposed between the respective dating-wheel and stem and a platen common to all of said wheels.

26. In a time-stamp, the combination of a clock-movement, time-wheel connected to the minute-shaft thereof, dating-wheel mounted on an independent parallel shaft, mechanism for rotating said dating-wheel and vertically-sliding key-stem for actuating said mechanism, and means for taking an impression simultaneously from all of said wheels.

27. In a time-stamp, the combination of a clock-movement, a time-printing wheel connected to the minute-arbor thereof and having an electrically-supported rim, a set of independently-mounted dating-wheels arranged adjacent to said time-printing wheel and with the opposite marking portion thereof arranged below the plane of the marking portion of the time-printing wheel, a platen common to all of said wheels and adapted during the printing stroke to depress the rim of the time-printing wheel so that its effective marking portion comes into substantially the same plane as the effective marking portions of the dating-wheels, and means for holding the descent of the rim of the said time-marking wheel during the said printing stroke.

28. In a time-stamp, the combination of a clock-movement, hour and minute printing wheels operatively connected to an arbor of said clock-movement, resilient connections between the rim and hub of each wheel, whereby the printing-carbons in the set of printing may receive a movement independent of said arbor, other adjusting key-actuated dating-wheels mounted independently of and disconnected from said first-mentioned printing-wheels, and a platen common to all said wheels.

29. In a time-stamp, the combination with hour and minute wheels, of a set of concentric dating-wheels, a pawl-and-ratchet mechanism connected with each dating-wheel and a set of vertically-sliding finger levers or stems for operating said pawl-and-ratchet mechanisms.

30. In a time-stamp, the combination of a shaft mounted to turn in suitable bearings, a ratchet-wheel and a dating-wheel secured to said shaft, a sleeve surrounding said shaft and provided with a second dating-wheel and a second ratchet-wheel, a second sleeve surrounding the first-mentioned sleeve and provided with a third dating-wheel and a third ratchet-wheel and a key-operated pawl engaging with each of said ratchet-wheels.

31. In a time-stamp, the combination with minute and hour printing wheels, a clock-movement for driving them, and a manually-actuated dating-wheel, of a counting mechanism for registering the number of times the dating-wheel has been actuated.

32. In a time-stamp, the combination of a clock-train, printing members, having characters indicating the time of day, progressively actuated by the clock-train so that, at any time, the characters thereon at the printing-point indicate the time, a platen, hand-operated means for, at any time, during a predetermined period of use, effecting pressure between the platen and the printing members for taking an impression of said characters, and means actuated by the clock-train for preventing such impression at the termination of the predetermined period of use.

33. In a time-stamp, the combination of a clock-train, printing members, having characters indicating the time of day, progressively actuated by the clock-train so that, at any time, the characters thereon at the printing-point indicate the time, a platen, hand-operated means for, at any time, during the predetermined period of use, effecting pressure between the platen and the printing members for taking an impression of said characters, means actuated by the clock-train for preventing such impression at the termination of the predetermined period of use and hand-operated device for throwing said last-mentioned means out of action to permit the taking of impressions during a further period of use.

34. In a time-stamp, the combination of a clock-train; printing mechanism controlled thereby and comprising members having characters indicating the time of day progressively actuated by the clock-train so that, at any time, the characters thereon at the printing-point will indicate the time and hand-operated means for, at any time during a predetermined period of use, effecting an impression from said characters and a locking device also controlled by the clock-train for holding said hand-operated means against movement at the termination of the predetermined period of use.

35. In a time-stamp, the combination of a clock-train; printing mechanism controlled thereby and comprising members, having charac-

ters indicating the time of day, progressively actuated by the clock-train so that at any time the characters thereon at the printing-point will indicate the time, and hand-operated means for, at any time during a predetermined period of use, effecting an impression from said characters; a locking device also controlled by the clock-train for holding said hand-operated means against movement at the termination of the predetermined period of use; and means for unlatching the locking device to permit the taking of impressions for a further period of use.

36. In a time-stamp, the combination with the clock-movement and the printing mechanism of a locking means thereby controlled by the clock-movement, a day-printing wheel included in said printing mechanism, and means connected with said day-printing wheel for advancing it one step and simultaneously unlatching the said locking means.

37. In a time-stamp, the combination with the clock-movement and the printing mechanism, of an automatically-operated mechanism for locking the printing mechanism out of operation, and a key-actuated mechanism for unlatching said mechanism and for simultaneously rotating one of the dating-wheels of the printing mechanism.

38. In a time-stamp, the combination with the clock-movement, the printing-wheel, and the platen, of a locking mechanism connected to the clock-movement and also to the platen for locking the latter against printing movement at a predetermined time.

39. In a time-stamp, the combination with the clock-movement, the printing-wheel, and the platen, of a locking mechanism controlled by the clock-movement and connected to the platen and operated at a predetermined time to lock the latter against movement, and means connected with the day-printing wheel for unlatching said locking mechanism at the same time that the day-wheel is rotated.

40. In a time-stamp, the combination with the clock-movement, the printing-wheel and the platen, a spring-detent locking mechanism, and a latch controlled by the clock-movement for preventing the said locking mechanism from acting until a predetermined time.

41. In a time-stamp, the combination with the clock-movement, printing-wheels and the platen, of a spring-actuated locking mechanism, a latch for holding said locking mechanism out of action, and a cam operated by the clock-movement for acting upon said latch at a predetermined time and causing it to release the spring-actuated locking mechanism and engage it with the said platen.

42. In a time-stamp, the combination with a clock-movement, printing-wheels and a platen, of a plunger carrying said platen, a bar or bar adapted to engage said plunger, a lever for operating said bar or bar, a spring-pressed rod connected to said lever, a locking-lever adapted to hold said rod, and a cam connected to the clock-movement for acting on the last-mentioned lever and releasing said spring-pressed rod so as to cause the bar or bar to engage with the plunger.

43. In a time-stamp, the combination with the clock-movement, the printing-wheel and the platen and its plunger of a locking bar or bar, a lever for moving the same, a spring-pressed rod controlling said lever, a locking-lever, a cam for acting upon the latter, a day-wheel key for turning the day-wheel, and extensions from said key to said spring-pressed rod for rotating the spring-actuated locking mechanism simultaneously with the rotating of the day-wheel.

44. In a time-stamp, the combination with the clock-movement, printing-wheels and the plunger and its platen, of a locking bar or bar, a lever for moving the same, a spring-pressed rod for actuating said lever, a locking-lever, a cam for actuating the latter, a key for turning the day-wheel, a wedge-rod connected with said key and a release-rod connected with said spring-pressed rod for rotating the locking mechanism.

45. In a time-stamp, means for automatically locking the platen against movement, and means for unlatching the platen when the printing-date of the stamp is changed.

46. In a time-stamp, the combination with a series of printing-wheels, some of which are actuated automatically by the time-movement and others by hand operation, the platen carrying with said wheels, and time-controlled mechanism for locking said platen, of means controlled by one of the hand-operated wheels for unlatching the platen and rotating the locking mechanism.

47. In a time-stamp, the combination of a clock-movement, printing mechanism, means for automatically locking said printing mechanism out of operation, hand-operated means for rotating said printing mechanism, and means controlled by said rotating means for automatically releasing the locking means.

48. In a time-stamp, the combination of a clock-movement, printing mechanism, and means for automatically locking said printing mechanism out of operation once in every twenty-four hours, hand-operated means for rotating said printing mechanism to change the day to be printed, and means controlled by said rotating means for automatically releasing the locking means.

49. In a time-stamp, the combination of a clock-movement, print-

ing-carbon, a hand-operated platen, and automatically-operated means for locking the platen against movement.

50. In a time-stamp, the combination of a clock-movement, printing-carbon, a hand-operated platen, and automatically-operated means controlled by the clock-movement for locking the platen against movement once in every twenty-four (24) hours.

51. In a time-stamp, the combination of a clock-movement, printing-carbon, a hand-operated platen, automatically-operated means for locking the platen against movement at a fixed time, and hand-operated means for unlatching the platen.

52. In a time-stamp, the combination of a clock-movement, printing-carbon, a hand-operated platen, automatically-operated means for locking the platen against movement, and means for automatically unlatching said platen when the printing-date of the stamp is changed.

53. In a time-stamp, the combination of a clock-movement, a printing-carbon, the setting of which is controlled by said clock-movement, a printing-carbon which is set by hand, a platen which cooperates with said printing-carbon, automatically-operated means controlled by the clock-movement for locking said platen against movement at twelve o'clock midnight, and hand-operated means for releasing said locking means.

54. In a time-stamp, the combination of a clock-movement, a printing-carbon, the setting of which is controlled by said clock-movement, a printing-carbon which is set by hand, a platen which cooperates with said printing-carbon, automatically-operated means controlled by the clock-movement for locking said platen against movement at twelve o'clock midnight, and means which are controlled by the setting of the hand-set printing-carbon to automatically release the locking means.

55. In a time-stamp, the combination of a clock-movement, a time-printing wheel which is automatically operated by said clock-movement, a day-printing wheel which is hand set or actuated, a platen which cooperates with said printing-wheels, means controlled by the clock-movement for locking said platen at twelve o'clock midnight, hand-operated means for setting said day-wheel, and means controlled by said hand-operated means for releasing said lock, whereby when the day-wheel is changed the locking means will be automatically released.

56. In a time-stamp, the combination with a clock-movement and the hour-marking wheel thereof, of a cam on the minute-shaft, a spring-pressed pawl-carrying lever adapted to be raised and released by said cam, a ratchet-wheel connected to said hour-marking wheel, a toothed wheel attached to said ratchet-wheel, a spring-pressed detent member having an arm or extension which is engaged in the path of vibration of the said pawl-carrying lever and so as to be depressed thereby to disengage the said detent when the hour-wheel is to be turned.

57. In a time-stamp, the combination of a clock-movement, printing-wheels which are moved automatically by said clock-movement, an ink-ribbon and a spring-supported ribbon-guide which normally maintains the ink-ribbon out of contact with the printing-wheels.

58. In a time-stamp, the combination with a clock, of printing-wheels, means for automatically rotating said wheels from said clock, a spring paper-support, and a ribbon-guide carried by said support.

59. In a time-stamp, the combination with a clock, of printing-wheels, means for automatically rotating said wheels from said clock, an operable spring paper-support, and a ribbon-guide carried by said support and adapted to guide the ribbon across the aperture in said support, the construction and arrangement being such that the ribbon is normally maintained by said guide away from the face of the printing-wheels and the wheels are actuated to come through the aperture in said support.

60. In a time-stamp a centrally-supported printing-wheel having a rigid marking-rim which is electrically connected to its center of rotation and adapted to move bodily independently of its center, combined with a time mechanism by which the wheel is driven.

61. In a time-stamp a centrally-supported printing-wheel having a rigid marking-rim which is electrically connected to its center of rotation so as to permit a bodily movement of said rim independently and transversely of its center, combined with a time mechanism by which the wheel is driven.

62. In a time-stamp a printing-wheel having a rigid hub, a rigid marking-rim, and electric connections between the hub and rim for causing the latter to move independently of the former, combined with a time mechanism by which the wheel is driven.

63. In a time-stamp a printing-wheel comprising a rigid hub, a rigid marking-rim, and spring-actuated connections therebetween, combined with a time mechanism by which the wheel is driven.

64. In a time-stamp, the combination of a centrally-mounted printing-wheel having a marking-rim connected to its center so as to have a movement independent thereof, means for halting the movement of the rim during the printing action, and a suspension or clock mechanism of which drives the printing-wheel.

65. In a time-stamp, the combination of a centrally-mounted printing-wheel having a marking-rim connected to its center so as to have a

movement independent thereof, a platen for then moving the rim, an actuator for halting the movement of the rim when actuated by the platen, and a spring-driven clock the mechanism of which drives the printing-wheel.

66. In a time-stamp, the combination of a bodily-movable, electrically and centrally mounted printing-rim, a platen for moving the rim, an actuator for halting said movement under the blow of the platen, and a spring-driven clock that drives the printing-wheel.

67. In a time-stamp, the combination of a clock having an ordinary spring-driven, a printing-wheel driven by the clock coincidentally with the minute-hand thereof and having upon its periphery raised time-indicating characters or types, an impression-platen and means whereby impact of the platen upon a type is combined radially to prevent material transmission of the shock of impact to the driving-shaft of the wheel.

68. In a time-stamp, the combination of a clock having an ordinary spring driving-drum, a printing-wheel driven by the clock coincidentally with the minute-hand thereof and having time-indicating characters or types upon the periphery each of which is electrically supported both with reference to its movement radially and the turning movement of the wheel and a platen between which and the face of the types impressions may be taken upon an interrupted shaft whereby the driving-shaft of the wheel is combined against shock of impact between the platen and the types and the turning movement of the wheel-shaft is not arrested at the moment of any such impression.

69. In a time-stamp, the combination of a time mechanism, a printing-wheel driven thereby and having upon its periphery raised time-indicating characters or types and resiliently-acting means interposed between the types and time mechanism acting to combine radial strain of impact against the types and to permit the uninterrupted movement of the time mechanism during the moment when an impression is being taken from any type.

70. In a time-stamp, the combination of a clock-movement, printing-wheels driven thereby, a casing within which the movement and wheels are contained having a cover with an opening for the printing-wheels and an operable ribbon-carrying guide, normally spring-supported to hold the ribbon out of contact with the wheels and readily attached at one edge to the cover, whereby the ribbon-guide and the contiguous part of the cover afford a guide for directing the paper into position when pushed along the face of the cover.

71. In a time-stamp, the combination of a time mechanism, a printing-wheel driven thereby and comprising a rim with type or characters thereon and a yielding connection between the rim and center which cushions the wheel-shaft against radial shocks and permits a continued movement of its center and the driving clock mechanism at the moment an impression is taken, a spring-supported ribbon-guide normally holding the ribbon out of contact with the wheel and an impression-platen.

72. In a time-stamp, the combination with minute and hour printing wheels, a clock-movement for driving them, a detent for locking them against reversed rotation and a manually-actuated dating-wheel of a counting mechanism for registering the number of times the dating-wheel has been actuated.

700,680. THREE RAIL CONNECTION FOR ELECTRIC RAIL-WAYS. CHARLES H. BROWN, Baltimore, Md., assignor of one-half to Harold P. Brown, Hagerstown, Md. Filed June 21, 1901. Serial No. 69,909. (No model.)

Claim.—1. The combination with consecutive parts of a main conductor having their contact-faces disposed in different directions, of a movable contact-piece and means for directing it into engagement with the said contact-faces during its movement along the consecutive parts of the main conductor, substantially as set forth.

2. The combination with consecutive parts of a main conductor having their contact-faces disposed in opposite directions, of a movable contact-piece and means for directing it into contact with the two oppositely-disposed faces of the parts of the conductor as it moves continuously along them, substantially as set forth.

3. The combination with consecutive parts of a main conductor, one of the parts being depressed below another and having their contact-faces oppositely disposed, of a movable contact-piece and means for directing it into contact with the oppositely-disposed faces of the parts of the conductor as it moves continuously along them, substantially as set forth.

4. The combination with consecutive parts of a main conductor, one depressed below the other and having their contact-faces oppositely disposed, of a downwardly-biased guide connecting the said parts of the conductor and a contact-rod adapted to engage the guide as it moves continuously along the conductor, the said rod being yieldingly supported to permit it to be driven by the guide into contact with the depressed part of the conductor, substantially as set forth.

6. The combination with consecutive parts of a main conductor located upon opposite sides of a track and movable contact-pieces arranged to move along the opposite sides of the track, of means under the control of a contact-piece on one side of the track for throwing a contact on the opposite side of a track into contact with the conductor, substantially as set forth.

6. The combination with consecutive parts of a main conductor located upon opposite sides of a track, of intermediate mechanism arranged to set the conductor on one side of the track in position to make contact, before contact is broken on the opposite side of the track, substantially as set forth.

7. The combination with consecutive parts of a main conductor located upon opposite sides of a track, one of the said parts being provided with a movable portion, of a device connected with said movable portion and arranged to be operated to throw the movable portion into position to make contact before contact is broken at the track, substantially as set forth.

8. The combination with consecutive parts of a main conductor located upon opposite sides of a track, one of the parts being depressed below the other and provided with a movable portion, of a device at the opposite side of the track from the movable portion and under the control of a contact-piece on that side of the track, to operate the said movable portion of the conductor to throw another side into engagement with the depressed part of the conductor, substantially as set forth.

9. A sliding contact-piece composed of harder and softer metals alternately disposed and exposed at its contact-face, substantially as set forth.

10. A sliding contact-piece comprising harder and softer metals alternately disposed, the harder metals being arranged obliquely to the longitudinal axis of the piece and exposed on its contact-face, substantially as set forth.

11. A sliding contact-piece having oppositely-disposed contact-faces, a vertically-movable shoe-support and means for holding the vertically-movable support under pressure to force the shoe into engaging contact both upwardly and downwardly, substantially as set forth.

12. A sliding contact-piece, a plurality of rods for supporting the shoe, each rod being provided with a spring, a support and means interposed between the support and the spring and rod for holding the shoe under the pressure of the spring in each of two opposite directions, substantially as set forth.

13. A sliding contact-piece support comprising a primary support, a rod connected with the shoe free to move relatively to said support, a spring surrounding the rod, washers located intermediate of the spring and the primary support at the opposite ends of the spring and free to move relatively to the rod, and adjustable stops on the rod forming abutments for the washers but free to move relatively to the primary support, substantially as set forth.

700,690. SWITCHING LATCH. JAMES P. HOGAN, JR., JR., assignor to American Manufacturing Co., a partnership consisting of Geo. C. Hoad and Charles W. Rogers, JR., JR. Filed Nov. 13, 1900. Serial No. 22,022. (No model.)

Claim.—1. The combination in a sectional ladder of one section the end of which overlaps the side of the end of another section, a loose rotatable ring mounted on the overlapping section, a fixed collar on one end of said ring adapted to engage one side of the overlapping section, and a fixed laterally-rotatable non-rotatable collar on the opposite end of said rotatable ring adapted to engage the other side of the overlapping section, substantially as and for the purpose set forth.

2. In a sectional ladder, the combination of overlapping ends having U-shaped recessed flanges, a fixed collar on the outer face of said flange, a loose rotatable ring extending through one side bar and having a collar on its outer end adapted to enter the recessed plate at one side of the ladder section, and a screw-thread on its inner end, a non-rotatable sleeve extending through the other side bar and having a collar on its outer end adapted to enter the recessed plate at the other side of the ladder-section, and an internal screw-thread on its inner end to receive the screw-thread on the lower end of the loose ring, substantially as and for the purpose set forth.

3. The combination in a sectional ladder, of side-bar sections having slots in their upper ends adapted to engage the round O in an overlapping section A provided with slots in the lower end thereof, a cam-tumbler plate D on the outside of each of the slots a, a loose rotatable round E extending through and beyond one of the side bars of the section B and having a beveled roller c on its outer end adapted to enter the recess d on the plate D at one side of the ladder-section A, and a screw-thread c' on its inner end, a non-rotatable sleeve F extending through and beyond the other side bar of the section B and having a beveled roller c' on its outer end adapted to enter the recess d on the plate D at the other side of the ladder-section A, and an internal screw-thread in its inner end adapted to receive the screw-thread c' on the loose ring E, substantially as and for the purpose set forth.

700,691. GARAGE-FASTENER. EDWIN E. BARNETT, Mechanicsville, Md., assignor to Peter H. Hartman and Anthony Barnett, Mechanicsville, Md., and Samuel G. Olson, Reading, Pa. Filed Oct. 15, 1901. Serial No. 79,182. (No model.)

Claim.—1. As a new article of manufacture, a carpet-fastener comprising a strip, and hinged jaws arranged at intervals and provided with engaging portions extending through the strip, substantially as described.

2. As a new article of manufacture, a carpet-fastener comprising a strip, and jaws hinged at the back of the strip and arranged at intervals and extending forward over the strip and provided with front carpet-engaging portions, substantially as described.

3. A carpet-fastener comprising a strip, and a series of clamps arranged at intervals on the strip, each clamp being provided with a hinged jaw having an engaging portion extending through the carpet and the strip and projecting beyond the bottom of the latter, whereby it is adapted to be embedded in the floor, substantially as and for the purpose described.

4. A carpet-fastener comprising a strip, and clamps arranged at intervals, each clamp consisting of a base-plate extending across the bottom of the strip and provided with an upwardly and inwardly extending front portion arranged on the upper face of the strip, and a jaw hinged to the base-plate at the back of the strip and extending forwardly over the top of the strip and having a carpet-engaging outer or front portion, substantially as described.

5. A carpet-fastener comprising a strip, and clamps arranged at intervals, each clamp consisting of a base-plate extending across the bottom of the strip and provided with an upwardly and inwardly extending front portion arranged on the upper face of the strip, and jaws hinged to the base-plate at the back of the strip and extending forwardly over the top of the latter and provided at its outer or distal end with a depending engaging portion extending through the base-plate and the strip and adapted to engage a carpet, substantially as described.

6. In a carpet-fastener, a carpet-engaging clamp composed of a base-plate provided with an inwardly and upwardly extending front portion,

and base-plate being also provided in its front and bottom portions with openings, and a clamping-jaw hinged to the back of the base-plate and provided with an engaging portion depending from the jaw and arranged to extend through the said openings, substantially as described.

7. In a carpet-fastener, a clamp composed of a base-plate, and a jaw hinged at the back of the base-plate and having a depending front portion adapted to engage the carpet and extending through an opening of the base-plate and engaging the latter, said depending front portion being also extended below the base-plate and adapted to be embedded in the floor, where its engagement with the latter will assist in retaining it in engagement with the base-plate, substantially as described.

8. In a carpet-fastener, a carpet-engaging clamp composed of a base-plate provided with an inwardly and upwardly extending front portion, said base-plate being also provided in its front and bottom portions with aligned openings, and a clamping-jaw hinged to the back of the base-plate and provided with an engaging portion depending from the jaw and arranged to extend through the said openings to engage the floor, and provided with a notch forming a shoulder for engaging the front portion of the base-plate, substantially as described.

700,692. GARAGE. CHARLES E. JENNISON, Vancouver, Ind., assignor of one-half to P. H. Walton and C. C. Walton, Windsor, Ind. Filed Nov. 13, 1901. Serial No. 22,022. (No model.)

Claim.—In a cabinet of the character described, the combination with the body portion thereof, provided at its upper and lower edges with integral molding-heads and with intermediate base-ports having dovetail grooves open at their lower ends and closed at their upper ends, of handle-attaching base mounted in said grooves and dovetailed in cross-section, substantially as set forth.

700,693. SEWING-MACHINE. THOMAS E. KERR, Boston, Mass., assignor to Tongue Lock Sewing Machine Company, a Corporation of Maine. Filed Oct. 1, 1901. Serial No. 77,212. (No model.)

Claim.—A machine of the character specified comprising loop-forming mechanism including an oscillating hooked needle adapted to draw a loop through an upper and through the "between substance" of a sole,

and hold the loop over the sole, a loop-spreader composed of two members which can move laterally in opposite directions to expand and contract the spreader, and spreader-actuating mechanism having provisions for moving the spreader as a whole to cause it to enter and recede from the loop and move toward and from the sole, and for sliding the said members laterally to expand and contract the spreader, substantially as described.

700,694. HINGE. RICHARD E. LE MAR, Palmyra, N. Y., assignor to John W. Dunham and Joseph E. Dunham, Palmyra, N. Y. Filed July 3, 1901. Serial No. 67,888. (No model.)

Claim.—1. A hinge, comprising a fixed member provided with opposite eyes, a plate passed through the eyes, a movable member having an eye located between the former eyes and receiving the plate, said movable member having a vertical sliding movement and a swinging movement upon the plate, and an independently-adjustable cam device disposed concentrically with respect to the plate and having an upwardly-inclined portion lying in the path of the swinging movement of the movable member, the highest point of the cam portion terminating in a notch or seat for the reception of a portion of the movable member.

2. A hinge, comprising a fixed member, a swinging and vertically-movable member, and a vertically-adjustable independently-mounted cam located in the path of the swinging movement of the movable member.

3. A hinge comprising a fixed member, a swinging and vertically-movable member, and an independently-adjustable substantially conical member having its upper edge located in the path of the swinging movement of the movable member and inclined to form a cam edge, the opposite ends of the member being formed into attaching elements.

4. In a hinge, the combination of a fixed member having opposite eyes, a movable member having an eye located between the opposite eyes, a plate passed through the eyes, the movable member having a pivotal and a sliding movement upon the plate, a helical spring embracing the plate and bearing in opposite directions against the upper eye of the fixed member and the eye of the movable member, the latter having a roller mounted at its lower edge, and an independently-mounted cam device consisting of a conical part located concentrically with the plate, having its upper edge in the path of the roller at a point between the ends of the plate, and provided with an inclined or cam portion which terminates at its highest point in a notch or seat, the opposite ends of the conical part being extended into attaching elements.

700,695. MULTIPLE-POLE BOX. JAMES B. LITTLE, Baltimore, Md., assignor of one-third to William G. Gooding, York, Pa. Filed Aug. 28, 1901. Serial No. 73,978. (No model.)

Claim.—The herein-described multiple-pole device, comprising a cylindrical box, a, provided at one side with an opening, g; a vent-block, v, fitted in said opening and provided with a concave inner face, v'; a cylindrical roller mounted in said box and spaced from the end thereof, and whose circumference conforms to and contacts with said concave face, v', and has a plurality of longitudinal depressions, g', substantially right-angled face-bearing plates attached to the ends of said roller and provided with contact-lugs projecting toward the ends of the box; flex-wires held by said plates and extending through said depressions, g, whereby the concave inner face, v', and the surrounding walls of the respective depressions may separate one flex-wire from the others; contacts, l, secured

in said bar on opposite sides of and in alignment with said vent-blank; and carbon terminals mounted to slide in said casings and spring-pressed outwardly into engagement with one set of contact-taps at a time, as set forth.

700,696. FIRE-EXTINGUISHER. ROBERT H. MARTIN, Dayton, Ky., assignor to the American Chemical Fire Extinguisher Company, Cincinnati, Ohio, a corporation of Ohio. Filed June 2, 1900. Serial No. 14,896. (No model.)

Claim.—1. In a chemical fire-extinguisher, the combination, with an alkali and an acid receptacle, of a holder for the acid-receptacle to contain same in a fixed position submerged within and below the surface of the liquid in the alkali-receptacle, a weighted diving-bell sealing device for said acid-receptacle, and means to permit said sealing device to drop away from the mouth of said receptacle when the fire-extinguisher is inverted without displacement from said acid-receptacle, substantially as shown and described.

2. In a chemical fire-extinguisher, the combination with the alkali and acid receptacles, of a holder for the acid-receptacle to contain same in fixed position within the alkali-receptacle, and a bell-mouthed cover for the acid-receptacle provided with a rod, and an arm on the holder to guide same, whereby the cover may be prevented from displacement when the receptacles are inverted, substantially as described.

3. In a fire-extinguisher, the combination with a liquid-holding tank, of an acid-bottle and a weighted diving-bell sealing device therefor adapted to be submerged within and below the surface of the liquid in said tank, the said sealing device adapted to fall away from the acid-bottle when the tank is inverted, substantially as described.

4. In a fire-extinguisher, the combination with a liquid-holding tank, of an acid-bottle and a weighted diving-bell sealing device therefor, adapted to be submerged within and below the surface of the liquid in said tank, the said sealing device adapted to fall away from the acid-bottle when the tank is inverted, substantially as described.

700,697. RAY-PRESS. RAY W. HENNER, Ann Arbor, Mich., assignor of one-half to Percy W. Henner, Ann Arbor, Mich. Filed Dec. 28, 1891. Serial No. 66,957. (No model.)

Claim.—1. In a ray-press, the combination of a plunger operating longitudinally of the frame of the machine, means for actuating said plunger,

for, a connecting-rod between said plunger and a walking-beam, a perpendicular operating plunger actuated by the walking-beam, said walking-beam being divided into two parts and having a spring interposed between the two parts uniting the separation of the two parts at the pivotal center of motion, whereby the perpendicular plunger is enabled to yield on encountering an undue resistance, substantially as described.

2. In a ray-press, a frame containing therein a hopper or tank to receive the material to be packed, a packing-chamber into which said material is compressed, a roller in advance of the top of the said chamber to assist in guiding and transferring the material into the packing-chamber, the roller having a relatively larger diameter than said being mounted upon a fixed axis, a yielding spring or springs mounted above and impinging against said roller whereby said roller is enabled to not only rotate but swing toward the edge of the cover of the packing-chamber, substantially as and for the purpose described.

3. In a ray-press, the combination of a longitudinally operating plunger, means for actuating said plunger, a connecting-rod between said plunger and a walking-beam, a perpendicular operating plunger actuated by the walking-beam, a walking-beam divided into two parts, said parts having at one point a pivotal connection, and at the other point an elastic resistance tending to prevent their separation, substantially as and for the purpose specified.

700,698. TAP-ROCKER. RUSSELL H. MONTGOMERY, South, E. J. Filed Oct. 14, 1891. Serial No. 71,701. (No model.)

Claim.—1. A tap-holder comprising a case having a tap-opening, a rotary spring-actuated tap-holding drum in the case, a friction-surface for the drum, an axially-movable member and a spring operating to force the drum into frictional engagement with said surface, said member having an extension adapted to be engaged by one of the end walls of the case whereby the compression of said wall moves the member against the action of its spring to release the drum.

2. A tap-holder comprising a case having a tap-opening, a hollow bearing, a friction-surface, a spring-tensioned brake member movable axially in the bearing, a spring-actuated drum normally impinged between the friction-surface and brake member and carrying a tap-movable through said opening, and a yielding portion forming part of the case arranged to be compressed against the brake member to move the same against the action of its spring to release the drum.

3. A tap-holder comprising a case, opposite disks within the case, a hollow bearing projecting from one of the disks, a spring-actuated drum mounted on the bearing and carrying a tap, a friction-surface between the drum and one of the disks, a brake member and its actuating spring between the drum and other disk to normally hold said drum in engagement with said surface, and means on the case to engage and move the brake member against the action of its spring to release the drum.

4. A tap-holder comprising a case having a tap-opening, a bearing within the case having longitudinal slots, a spring-actuated drum rotatably mounted on said bearing and carrying a tap to be wound thereon, a part having lateral arms mounted in said bearing, said arms adapted to rest normally in frictional contact with one face of the drum and means for forcing said arms out of frictional contact with the drum for the purpose specified.

5. A tap-holder comprising a case having a tap-opening, a bearing within said case having longitudinal slots, a spring-actuated drum rotatably mounted on said bearing and carrying a tap adapted to be wound thereon, a part having lateral arms mounted in said bearing, said arms engaging with the slots and resting normally in frictional contact with one of the faces of the drum, a spring mounted on said part, one end engaging with said arms and the other end with the wall of the case for the purpose of holding said arms in frictional contact with the drum for the purpose specified.

6. A tap-holder comprising a case having a tap-opening, a tubular bearing within said case having longitudinal slots, a spring-actuated drum rotatably mounted on said bearing and carrying a tap adapted to be wound thereon, a part having an axially-extending arm adapted to be engaged by the adjacent wall of the case and lateral arms mounted in said bearing, said arms engaging with said slots and resting normally in frictional contact with one of the faces of the drum, a spring mounted

of an aid post within the bearing, one end engaging with the said drum and the other end against the wall of the case for the purpose specified.

700,699. TYPE-JUSTIFYING MACHINE. FRANK MCCLINTOCK, Mount Vernon, N. Y., assignor, by mesne assignments, to Shreve & Hoyt and Peck House, New York, N. Y. Filed June 11, 1891. Serial No. 64,184. (No model.)

Claim.—1. The combination with the face-plate, of the line-holder arranged to travel thereon, having suitable type-cases and provided with a movable and adjustable face-plate, by means of which the type-cases may be enlarged or made smaller at its base as it will so as to receive type characters of any desired size.

2. The combination with the face-plate, of the line-holder arranged to travel thereon, having a suitable type-case the side wall of which is beveled at the base, as or to act on the face of each character as it is inserted in the type-case.

3. The combination with the face-plate, of the line-holder arranged to travel thereon, having a suitable type-case and provided with a movable and adjustable face-plate, the side wall of which is beveled at the base, as or to act on the face of each type character, as it is inserted in the type-case, and by means of which the type-cases may be enlarged or made smaller at will so as to receive type characters of any desired size.

4. The combination with the face-plate of the line-holder arranged to travel thereon, and a movable plate forming the bottom and side of the type-channel supported on the line-holder by pins arranged to slide in suitable openings therein, and provided with device for actuating the plate; and suitable springs for holding the plate normally in an advanced position with respect to the line-holder.

5. The combination with the face-plate, of the line-holder arranged to travel thereon; and a movable plate forming the bottom and side of the type-channel supported on the line-holder in suitable channels at either end and having screw-pins arranged to slide in openings therein, and provided with means for actuating the same; and suitable springs for holding the plate normally in an advanced position, with respect to the line-holder.

700,700. TYPE-JUSTIFYING MACHINE. FRANK MCCLINTOCK, Mount Vernon, N. Y., assignor, by mesne assignments, to Shreve & Hoyt and Peck House, New York, N. Y. Filed June 11, 1891. Serial No. 64,185. (No model.)

Claim.—1. In a type-justifying machine, the combination of an independent wedge-shaped space-bar; means for driving the same a certain distance; means for then arresting the same; means for holding and guiding the thin end of the space-bar; means for holding the rear end of the space-bar while this is being done; means for driving the space-bar still further to its final position; and means for withdrawing the holding device from the rear end of the space-bar when the operation is completed.

2. In a type-justifying machine, the combination of an independent wedge-shaped space-bar; means for driving the same a certain distance; means for then arresting the same; means for holding the rear end of the said space-bar while this is being done; means for driving the space-bar still further to its final position; means for withdrawing the holding device from the rear end of the space-bar when the operation is completed; and means for advancing the rear end of the space-bar after releasing, as or to cause the space-bar to assume its proper position in the line-holder.

3. In a type-justifying machine, the combination of an independent wedge-shaped space-bar; means for driving the same a certain distance; means for then arresting the same; means for thereupon advancing the forward end of the space-bar a certain distance, and for holding the rear end of the said space-bar while this is being done; means for driving the space-bar still further to its final position; and means for withdrawing the holding device from the rear end of the space-bar when the operation is completed.

4. In a type-justifying machine, the combination of an independent wedge-shaped space-bar; means for driving the same for a certain distance; means for then arresting the same; means for thereupon advancing

ing the forward end of the space-bar a certain distance, and for holding the rear end of the said space-bar while this is being done; means for driving the space-bar still further to its final position; means for withdrawing the holding device from the rear end of the space-bar when the operation is completed; and means for advancing the rear end of the space-bar after releasing, as or to cause the space-bar to assume its proper position in the line-holder.

5. In a type-justifying machine the combination of an independent wedge-shaped space-bar; means for driving the same a certain distance; means for then arresting the same; means for holding and guiding the thin end of the space-bar; means for holding the rear end of the space-bar while this is being done; means for driving the space-bar still further to its final position; and means for withdrawing the holding device from the rear end of the space-bar when the operation is completed.

6. In a type-justifying machine, the combination of an independent wedge-shaped space-bar; means for driving the same a certain distance; means for then arresting the same; a spring-lever, operated by the space-bar-opening device, for holding and guiding the space-bar during the operation of insertion; means for thereupon advancing the forward end of the space-bar a certain distance and for holding the rear end of the space-bar while this is being done; means for driving the space-bar still further to its final position; and means for withdrawing the holding device from the rear end of the space-bar when the operation is completed.

7. The combination of a sliding plate arranged to slide vertically in suitable ways in the end plate; a space-bar-elevating plate, attached to and sliding vertically with the same; means for actuating the same substantially as described, and a spring device, substantially as described, retained by the wedge when it rises, for moving the rear end of the wedge forward after the operation of insertion has been completed.

8. In a type-justifying machine, the combination of an independent wedge-shaped space-bar; means for driving the same a certain distance; means for then arresting the same; means for holding and guiding the thin end of the space-bar; means for holding the rear end of the space-bar while this is being done; means for driving the space-bar still further to its final position; means for withdrawing the holding device from the rear end of the space-bar when the operation is completed; and a spring device, substantially as described, retained by the space-bar when it rises, for moving the rear end of the space-bar forward after the operation of insertion has been completed.

9. The combination of a sliding space-bar driven, arranged to slide horizontally on the end plate; means substantially as described, for operating the same; and a spring-lever, operated by the arm of the space-bar-opening device, for holding and guiding the space-bar during the operation of insertion.

10. The combination of a sliding plate, arranged to slide vertically in suitable ways in the end plate; a space-bar-cleaving plate, attached to and sliding vertically with the same; a sliding space-bar driver, arranged to slide horizontally on the end plate; a bell-crank lever, attached to the frame-plate, engaging at one end with the vertically-sliding cleaving-plate, and at the other end with the horizontally-moving space-bar driver; means substantially as described, for causing the space-bar driver to be held in a constantly-advanced position; and means, actuated at the will of the operator, for causing one arm of the lever to raise the cleaving mechanism and the other arm to retract the space-bar driver, and to thereupon advance the space-bar driver and lower the cleaving-plate, substantially as described.

11. The combination of a sliding plate, arranged to slide vertically in suitable ways in the end plate; a space-bar-cleaving plate, attached to and sliding vertically with the same; a sliding space-bar driver, arranged to slide horizontally on the end plate; a pivoted bell-crank lever composed of two independent arms held together by a spring, attached to the frame-plate, engaging at one end with the vertically-sliding cleaving-plate, and at the other end with the horizontally-moving space-bar driver; means substantially as described, for causing the space-bar driver to be held in a constantly-advanced position; and means, actuated at the will of the operator, for causing one arm of the lever to raise the cleaving mechanism and the other arm to retract the space-bar driver, and to thereupon advance the space-bar driver and lower the cleaving-plate, substantially as described.

12. The combination of a sliding plate, arranged to slide vertically in suitable ways in the end plate; a space-bar-cleaving plate, attached to and sliding vertically with the same; a sliding space-bar driver, arranged to slide horizontally on the end plate; a bell-crank lever, attached to the frame-plate, engaging at one end with the vertically-sliding cleaving-plate, and at the other end with the horizontally-moving space-bar driver; means substantially as described, for causing the space-bar driver to be held in a constantly-advanced position; and means, actuated at the will of the operator, for causing one arm of the lever to raise the cleaving mechanism and the other arm to retract the space-bar driver, and to thereupon advance the space-bar driver and lower the cleaving-plate, and for stopping the movement of the parts, at desired intervals, substantially as described.

13. The combination of a sliding plate, arranged to slide vertically in suitable ways in the end plate; a space-bar-cleaving plate, attached to and sliding vertically with the same; a sliding space-bar driver, arranged to slide horizontally on the end plate; a bell-crank lever, attached to the frame-plate, engaging at one end with the vertically-sliding cleaving-plate, and at the other end with the horizontally-moving space-bar driver; means substantially as described, for causing the space-bar driver to be held in a constantly-advanced position; a suitable type-cam; a rotating shaft, actuated from a suitable source of power; a toothed collar, secured to the said driving-shaft, the distance between the teeth of which are properly proportioned with respect to the revolutions of the type-cam; a cam rotating loosely on said driving-shaft; a roller attached to the bell-crank lever, and arranged to be moved by the movement of the said cam; a clutch mechanism for causing the cam to rotate with the fixed collar through a single revolution; and means for throwing the clutch mechanism into engagement at the will of the operator.

14. In a type-justifying machine, the combination of an independent wedge-shaped space-bar; means for driving the same a certain distance; means for then retracting the same; means for thereupon advancing the rear end of the space-bar while this is being done; means for driving the space-bar still further into its final position; means for holding the forward end of the said line-holder while being so driven forward, and for holding it in its final position, and means for withdrawing the holding device from the rear end of the space-bar when the operation is completed.

15. In a type-justifying machine, the combination of an independent wedge-shaped space-bar; a spring-lever, operated by the space-bar-operating device, for holding and guiding the space-bar during the operation of insertion, provided at the end with a half-edged projection for driving down any preceding space-bar which has not been properly inserted in place, and means for advancing the space-bar substantially as described.

16. In a type-justifying machine, the combination of the frame-plate provided with the opening opposite the line-holder into which the front end of the space-bar projects, the rear end of which is beveled so as to force the end of the space-bar engaged therewith positively forward, a line-holder arranged to travel on said plate; space-bars inserted horizontally across the line-holder, and means substantially as described for inserting the space-bars one by one through the line-holder.

700,701. TYPE-JUSTIFYING MACHINE. FRANK McCLINTOCK, Mount Vernon, N. Y., assignor, by mesne assignments, to Edwin C. Hoyt and Felix Rosen, New York, N. Y. Filed June 11, 1901. Serial No. 64,188. (No model.)

Claim.—1. The combination of a movable space-bar divided longitudinally into compartments containing spaces of the different class used; the dotted front plate on said space-bars, having beveled position-walls; a space-jacking bar having its lower edge beveled and adapted to eject a single space from any one of the space-compartments; a space-jacking lever composed of two arms, one of which is pivoted to the bed of the machine at one end and carries the space-jacking bar at the other end, and the other of which is pivoted to the first arm, and is limited in motion by a stop and is provided on its outer end with a roller engaging the actuating-cam; device for holding the two arms of the lever normally in a rigid position; and an actuating-cam upon the rotating justifying-shaft, substantially as described.

2. The combination of a space-jacking lever composed of two arms, one of which is pivoted to the bed-plate of the machine and carries the space-jacking bar, and the other of which is pivoted to the first arm and is limited in its movement by a stop at one end and provided at its other end with a roller engaging with the actuating-cam, and device for holding the two arms of the lever normally in a rigid position and releasing the upper arm in case of any obstruction to the normal movement of the lever.

3. The combination of a space-rack; device for jacking the space therefrom, substantially as described; a rotating justifying-shaft; a suitable cam attached to and rotating with the said shaft; a lever for actuating the space-jacking device, composed of two arms, one of which is pivoted to the bed-plate of the machine and actuates the space-jacking device, and the other of which is pivoted to the first arm, is limited in its movement by a stop at one end, and is provided at its other end with a roller engaging with the cam on the justifying-shaft; and device for holding the two arms of the lever normally in a rigid position and releasing the upper arm in case of any obstruction to the normal movement of the lever.

700,702. PICTURE-EXHIBITOR. THOMAS T. McNEVART, Fayetteville, N. C., assignor of three-fourths to James E. Williams, Fayetteville, N. C. Filed July 15, 1901. Serial No. 65,208. (No model.)

Claim.—1. In a picture-exhibitor, the combination with the revolving carrier having hub portions, and members 34, projected radially from the hub, and members 34 having plates 34', projected inward in a plane with the longitudinal axis of the carrier; of the U-shaped holders formed of flexible material, having edges 35', to slip into or off of members 34', for the purposes described.

2. In an exhibitor of the character described the combination with the object-carrier, and a lamp-circuit; of a drive mechanism for the carrier, said drive mechanism having a governor device connected with and operated by the drum mechanism for controlling the lamp-circuit, whereby to cut out the lamp in case of stoppage of the drive mechanism or for any cause, for the purposes specified.

3. In an exhibitor as described the combination with the object-car-

rier and the lamp-circuit, and a motor mechanism for driving the object-carrier; of an automatically-adjustable contact-maker connected with and operated by the motor normally out of electrical circuit held to cooperate with the motor, and adapted to make contact and close the lamp-circuit when the motor is put into operation, and break the circuit when the motor stops, as set forth.

4. The combination with the object-carrier, and the motor mechanism, and the electric-light circuit within the casing; of governor device cooperating with the motor mechanism, said governor device including a suitable disk and a contact-maker for the electric-lighting current in the casing, said contact-maker having a spring-held member adapted to be engaged by the suitable governor-disk when the object-carrier motor mechanism is cut into motion, all being arranged substantially as above and for the purposes described.

700,703. FARE-REGISTER. ARTHUR E. FURMAN, Brooklyn, N. Y., assignor to Sterling Supply & Manufacturing Company, New York, N. Y., a Corporation of New York. Filed Feb. 7, 1902. Renewed Oct. 26, 1902. Serial No. 66,541. (No model.)

Claim.—1. In a fare-register of the type heretofore specified, the combination of an actuator, means for transmitting registering action therefrom including a separable connection, an actuator mechanism and permanent and trip registers so actuated, a disconnecting-lever for breaking said connection, and means for locking said actuator and therewith said bell mechanism and said permanent register when the trip-register is disconnected and for locking said lever when said actuator is out of its normal position of rest.

2. In a fare-register, the combination with a trip-register of a reciprocating actuator, intermediate mechanism for transmitting the registering action including a separable connection, a disconnecting-lever having a catch portion, and a double-acting lock in the form of an L-shaped lever having an overhanging end and a shoulder behind the same to coast with said catch portion, the other end of the locking-lever projecting in the path of said actuator when the trip-register is disconnected and causing therewith to render the disconnecting-lever locked by said overhanging end when the actuator is out of its normal position of rest.

3. In a fare-register, the combination of a permanent register, a trip-register, an actuator common to both, transmitting mechanism comprising a separable connection between said trip-register and the remainder, a pressing-spring for maintaining said connection, a disconnecting-lever for breaking the connection, and a springless actuator-lock in the form of a lever having an overhanging end and to coast with said disconnecting-lever.

4. In a fare-register, the combination of bell mechanism, a trip-register, an actuator common to both, transmitting mechanism comprising a separable connection between said trip-register and the remainder,

a pressing-spring for maintaining said connection, a disconnecting-lever for breaking the connection, and a springless actuator-lock in the form of a lever having an overhanging end and to coast with said disconnecting-lever.

5. In a fare-register of the type heretofore specified, the combination of an actuator mechanism, a permanent register, a trip-register and provided with one member of a two-stop in combination with a disconnecting-lever which moves said wheel axially and is provided with the other member of said two-stop.

6. In a fare-register of the type heretofore specified, a disconnecting-lever provided with one member of a two-stop in combination with a trip-register wheel provided with a two-stop member which normally revolves clear of the stop member on said lever, and movable axially by said lever to disconnect the trip-register and bring said stop member into one and the same plane.

7. In a fare-register of the type heretofore specified, the combination with the disconnecting-lever of an actuator-lever actuated thereby, a direction-indicator having its spindle provided with a star-wheel concentric with a cam portion having rounded ridges, and a spring-pressed pallet engaging with said cam portion to assist the component-lever.

8. In a fare-register, the combination of a direction-indicator rotating step by step on a horizontal spindle which carries a star-wheel having a cam portion with rounded ridges, an actuator-lever engaging on a pivot parallel to said spindle, means for oscillating the component-lever to effect the initial and final movements of the indicator, and a spring-pressed pallet engaging with said cam portion to effect an intermediate secondary movement.

9. In a fare-register of the type heretofore specified, the combination with a disconnecting-lever having an actuator extension of a direction-indicator having its spindle provided with a star-wheel comprising a cam portion with rounded ridges, an actuator-lever worked by said extension and engaging with said star-wheel to effect the initial and final movements of the indicator, a spring-pressed pallet engaging with said cam portion to effect a secondary intermediate movement of the indicator, and a spring engaging with said extension, substantially as heretofore specified.

700,704. DEVICE FOR TIGHTENING OR LOOSENING BOLTS OF TANKS, VANS, OR CLAMSHIPS. L. PARKER, Los Angeles, Cal. Filed June 17, 1901. Serial No. 64,508. (No model.)

Claim.—The device for tightening and loosening the heads of tanks, vans or analogous vessels, consisting of the combination of a hoop or band, movable, adjustable and flexible legs, the handles, and the legs, respectively carried upon each end of said hoop or band, the wedges in the handles, the legs being formed at their lower ends with an upturned nose to press the wedge within each box or handle relatively with the legs, the tightening screws and nuts, the upper ends of the legs being formed as upturned receptacles for the nuts and tightening-screws, all operating together in the manner used for the purposes substantially as set forth.

700,705. SHOE-GRINDER. CHARLES L. FORTSON, Fulton, N. C., assignor of one-half to William E. Smith, Lyons, Iowa. Filed Aug. 4, 1901. Serial No. 18,897. (No model.)

Claim.—The combination of levers pivoted intermediate their ends, the one end of one of the levers extending at an angle to the length of said lever and provided with a stretcher-band, and the corresponding end

of the other lever being formed with an extended curved portion which curves in the direction toward the stretcher-band, substantially as set forth.

700,706. STOVE-RASH FASTENER. EDWARD C. GUNST, Minneapolis, Minn. Filed Oct. 26, 1902. Serial No. 24,092. (No model.)

Claim.—A stove-rash fastener comprising a plate to be secured upon the window-frame, and provided with a stud and a lug having an outwardly-turned cam-face, in combination, with a spring-arm that slides automatically upon said stud when the rash is pushed open and having a hook at one end and a loop at the other and pivoted at an intermediate point upon the rash, said hook engaging said stud and said loop engaging the stud and flange said arm when the rash is open to hold the hook firmly upon said stud, and said loop being adapted to receive said lug and slide over its cam-face and draw the rash to its rest when said arm is drawn in and turned down over said stud to close the rash, substantially as described.

700,707. FILE. ALFRED A. RAYMOND, Chicago, Ill. Filed July 28, 1901. Serial No. 68,614. (No model.)

Claim.—1. In an expanding file-core, the combination with the longitudinal sections thereof, of hinges uniting the said sections and permitting relatively longitudinal movement thereof, whereby the said sections may be separated or collapsed, substantially as described.

2. In an expanding file-core, the combination with the longitudinal sections thereof, of hinges uniting the said sections and permitting relatively longitudinal movement thereof, whereby the said sections may be separated or collapsed, and a key for maintaining the sections of the file-core in a separated relation, substantially as described.

3. In an expanding file-core, the combination with the longitudinal sections thereof, of hinges uniting the said sections and permitting relatively longitudinal movement thereof, whereby the said sections may be separated or collapsed, one of the said sections being provided with a transverse section of upon which the other section may bottom when the said sections are in a separated relation, substantially as described.

4. In an expanding file-core, the combination with the longitudinal sections thereof, of hinges uniting the said sections and permitting relatively longitudinal movement thereof, whereby the said sections may be separated or collapsed, and a key for maintaining the sections of the file-core in a separated relation, one of the said sections being provided with a transverse section of upon which the other section may bottom when the said sections are in a separated relation, substantially as described.

5. A file-core having its tip longitudinally movable with respect to the remainder of the file-core, and having telescoping engagement therewith, substantially as described.

6. A tapering file ending or shell formed in relatively longitudinally movable lengths, substantially as described.

7. A tapering file ending or shell formed in relatively longitudinally movable telescoping lengths, substantially as described.

8. A tapering file-core having a tip exterior to said ending and longitudinally movable relatively thereto, substantially as described.

9. A tapering file-core having its tip longitudinally movable with respect to the remainder of the file-core, and having telescoping engagement therewith, substantially as described.

10. The combination with an expanding file-core, of a shell or ending adapted to surround said core, and a tip against which said core is adapted to press, said shell and tip being longitudinally movable relatively to each other, substantially as described.

11. The combination with an expanding file-core, of a tapering shell or ending adapted to surround said core, and a tip against which said core is adapted to press, said shell and tip being longitudinally movable relatively to each other, substantially as described.

12. The combination with a shell or ending, of an expanding file-core composed of longitudinal sections, means interposed between said sections, whereby upon the relatively longitudinal movement of the same the sections of the file-core may be expanded or collapsed, and a tip against which said core is adapted to press, covering the end of said ending and longitudinally movable relatively thereto, substantially as described.

13. A tapering file ending or shell formed in relatively longitudinally movable lengths, in combination with a filling of concrete or similar material, substantially as described.

14. A composite file composed of a tapering sectional shell or ending filled with concrete or similar material, substantially as described.

700,708. COIL-DRUM. HARRY BOWMAN, Philadelphia, Pa. Original application filed Feb. 15, 1901. Serial No. 65,968. Divided and this application filed Oct. 16, 1902. Serial No. 73,473. (No model.)

Claim.—1. A coil-drum consisting of a non-conducting surrounding, wires passing therein from opposite ends, plugs connected to said wires and located by the surrounding, and particles of carbon and a series of steel balls located in the space between the plugs.

2. A coil-drum consisting of a non-conducting surrounding, conducting-wires entering therein, plugs mounted therein and connected to said wires and forming a pocket therebetween, and particles of granulated carbon and steel balls located in said pocket.

700,709. PICTURE-PROJECTING APPARATUS. GEORGE W. SMITH, Evanston, Ill., and WILLIAM A. SCHUBERT, St. Paul, Minn.; said Schubert assignor to said Smith. Filed June 24, 1901. Serial No. 64,662. (No model.)

Claim.—1. A picture-strip for projecting apparatus comprising a plurality of picture-sections, and interposed sections of flexible material which allow the pictures to be placed in overlapped relation when fixed in the same direction, said sections consisting of narrow parts located at the sides of the strips and offering central spaces through which the pictures are exposed as the strip is unfixed.

2. A kinesiograph comprising a picture-strip which consists of a plurality of picture-sections bearing a series of pictures of the same scene or object and connected by interposed flexible sections of such length as to allow the picture-sections to be placed in overlapped relation when fixed in the same direction, supporting means for the folded strip, and pressing means acting against the rear of the folded strip when said picture-sections are exposed.

these and is their overlapped or folded position to hold the section which forms the face of the folded strip in position for projection and to advance the next section as shown in front of them as successively removed, the parts being so arranged that the strip may be rapidly unfixed and the picture-sections quickly exposed in succession by drawing upon the forward end of the strip so as to give the combination of motion in the projected pictures.

3. A kinesiograph comprising a picture-strip comprising a plurality of sections bearing a series of pictures of the same scene or object and connected by interposed flexible sections of such length as to allow the picture-sections to be placed in overlapped relation when fixed in the same direction, a magazine adapted to support the picture-sections when in their overlapped relation, and pressing means acting against the rear of the picture-strip to hold the picture-section which is at the front face of the folded strip in position for projection and to advance the next section as shown in front of them as successively removed, the parts being so arranged that the strip may be rapidly unfixed and the picture-sections quickly exposed in succession by drawing upon the rear end of said strip, so as to give the combination of motion in the projected pictures.

4. The combination with a projecting apparatus, of a holder adapted to contain a picture-strip, said holder being provided with an exit-disk for the picture-strip wider at its middle than at its end, and a movable pressure means to advance the picture-strip toward the exit-disk.

5. A kinesiograph comprising a holder adapted to contain a folded picture-strip, a wall or plate provided with a picture-opening and in which said picture-holder is attached, said holder being provided adjacent to the wall with an exit-disk, a pressure means for moving the pressure toward said opening to advance the folded strip so its end is withdrawn through said disk, thereby enabling the picture-strip to be rapidly withdrawn from the holder to expose the pictures on the strip in quick succession and thereby give the combination of motion in the projected pictures.

6. A kinesiograph comprising an object-lens, a source of light, a reflector in advance of said source of light, a picture-strip holder adapted to contain a folded picture-strip, an inclosure provided with a wall or plate containing a picture-opening in position to be illuminated by rays from said reflector, said picture-holder being secured to the said wall or plate in position to contain the folded picture-strip against the said opening and being provided with an exit-disk located adjacent to the said wall or plate, a pressure means for actuating the pressure acting to advance the same and the folded strip toward the said opening and to bring the pictures on the strip rapidly into place for projection when the strip is drawn rapidly from the holder to successively expose the pictures on the strip and to thereby give the combination of motion in the projected pictures.

7. A kinesiograph comprising an object-lens, a source of light, a reflector in advance of the source of light, a holder adapted to contain a folded picture-strip, an inclosure provided with a rear wall containing a picture-opening in position to be illuminated by the rays from said reflector, said holder being attached to said wall in position to hold the folds of the picture-strip against said opening and being provided with an exit-disk for the picture-strip located adjacent to said wall, guide-strips on said wall arranged at either side of said opening in position to engage the side edges of said picture-strip, a pressure, and actuating means for the pressure operating to advance the pressure and the folded strip toward the wall so the folds of the strip are rapidly withdrawn from the holder to successively expose the pictures on the strip and thereby give the combination of motion in the projected pictures.

700,710. WOVEN-WIRE-PRISM MACHINE. FRED SCHUBERT, Evanston, Ill. Filed Aug. 20, 1901. Serial No. 73,417. (No model.)

Claim.—1. In a frame-machine, the combination with a carriage, of a vertically-movable twister-head thereon, provided with means for carrying a quantity of wire, and means for moving the head vertically comprising automatic means for rotating the head periodically, substantially as and for the purpose set forth.

2. In a frame-machine, the combination, with a carriage, of a vertically-movable, dotted twister-head mounted thereon, provided with a wire-carrier, and means for moving the head vertically and periodically rotating it enough more than one or more complete revolutions to cause the slots in the wire to assume diametrically opposite positions relatively to the moving wire.

3. In a frame-machine, the combination, with a carriage, of a vertically-movable twister-head mounted thereon, a wire-carrier detachably connected with the head, the sides of which are provided with flexible fingers, a head movably held by said fingers, and means for moving the head vertically and rotating it at different horizontal strands of the frame.

4. In a frame-machine, the combination, with a carriage, of a vertically-movable twister-head mounted thereon, a wire-carrier detachably connected with the head, the sides of which are slotted longitudinally to

form flexible fingers at one end, the fingers usually standing out beyond the plane of the sides and having their tips bent forward, a head around the fingers to draw them toward as it is moved longitudinally toward the tips, a head adapted to be clamped between said tips, and means for moving the twister-head vertically and rotating it at different horizontal strands of the frame.

5. In a frame-machine, the combination, with a carriage, of a vertically-movable, longitudinally-slotted twister-head mounted thereon, a wire-holder secured to one end of the head concentrically to its axis and in communication with said perforation, and means for moving the head vertically and rotating it at different horizontal strands of the frame.

6. In a frame-machine, the combination, with a carriage, of a vertically-movable rotary twister-head, means for rotating the head at the different horizontal wires of the frame, a lock for holding the head against rotation, and a longitudinally-movable releasing apparatus for the lock.

7. In a frame-machine, the combination, with a carriage, of a vertically-movable dotted twister-head, a slotted bar through the head, the ends of which are slotted to register with the slots of the head, a chain for engaging with the head and holding the head against rotation, and means for moving the head between the horizontal wires of the frame and rotating it around them.

8. In a frame-machine, the combination, with a carriage, of a vertically-movable, longitudinally-slotted twister-head thereon, a slotted bar through the head, the ends of which are slotted to register with the slots of the head, a slide for engaging with the ends of the bar, and means for operating the slide.

9. In a frame-machine, the combination, with a carriage, of a vertically-movable twister-head, a chain for rotating the head and carrying it from one to the other of the horizontal wires of the frame, a wheel in engagement with said chain, and a lock for holding said wheel against rotation when the head is being moved from one to the other of the horizontal wires of the frame.

10. In a frame-machine, the combination, with a carriage, of a frame mounted to move vertically thereon, a peripherally-grooved twister-head in the frame, one end of which is provided with sprocket-teeth, a sprocket-wheel journaled on the frame, provided with a lock for periodically locking it against rotation, and a sprocket-chain for rotating the head and moving it from one horizontal wire to the other of the frame.

11. In a frame-machine, the combination, with a carriage, of a frame mounted to move vertically thereon, a twister-head in the frame provided with sprocket-teeth, a lock for holding the head against rotation, a sprocket-wheel on the frame provided with a stop, a pawl for engaging with said stop, a sprocket-chain in engagement with the wheel and head, and means for locking the head against rotation as it is being moved from one horizontal wire of the frame to another.

12. In a frame-machine, the combination, with a carriage, of a frame

mounted to move vertically thereon, a twister-head, and a sprocket-wheel on the frame, a slide and a pawl for locking the head and the wheel relatively against rotation, the slide being provided with a projection, a spring-actuated pin on the pawl for engaging with the projection, and a sprocket-chain for rotating the wheel and head and carrying them from one horizontal wire of the frame to the other.

13. In a frame-machine, the combination, with a carriage, of a frame mounted to move vertically thereon, a twister-head and a sprocket-wheel on the frame, means for locking the head and wheel against rotation, a slide for releasing said locking mechanism, a sprocket-chain for rotating the head and wheel and carrying them from one of the horizontal wires of the frame to another, and means for shifting the slide at the limit of the vertical movement of the frame.

14. In a frame-machine, the combination, with a carriage, of a frame mounted to move vertically thereon, a slotted twister-head and a sprocket-wheel on the frame, a slotted bar through the head and a pawl for the wheel, a slide provided with fingers and an inclined projection, the fingers being adapted to engage with the ends of the bar, a spring-actuated pin on the pawl for engaging with said projection, a sprocket-chain for operating the head and wheel, and means for shifting the slide at the limit of the vertical movement of the frame.

15. In a frame-machine, the combination, with a carriage, of a twister-head, a slide and a sprocket-wheel thereon, the wheel being provided with a cam, levers for moving the slide longitudinally, one end of each of which is adapted to be moved by the cam, and a chain for rotating the head and wheel and moving them from one horizontal wire of the frame to the other.

16. In a frame-machine, the combination, with a carriage provided with guides, a vertically-movable frame on the guides, a two-part twister-head, and a sprocket-wheel on the frame, one of the parts of the head being provided with sprocket-teeth and the other part with a wire-carrier, a sprocket-chain for rotating the wheel and head, and locking mechanism for holding them against rotation while they are being carried from one of the horizontal wires of the frame to another.

17. In a frame-machine, the combination, with a carriage, of a vertically-movable twister-head thereon, means for operating the head, two bars adapted to be placed upon opposite sides of the horizontal wire of the frame in position for engaging with the cam, and means for simultaneously moving said bars toward and from each other.

18. In a frame-machine, the combination, with a carriage, of a vertically-movable twister-head thereon, means for operating the head, two bars in the frame, one of which is provided with notched planes for engaging with the respective horizontal wires of the frame, interlocking levers for simultaneously moving the bars toward and from each other, and a foot-lever for operating said levers.

19. In a frame-machine, the combination, with a carriage provided with three sprocket-wheels, two of which are arranged in a vertical line and the other one is provided with a handle, a chain around said wheels, a vertically-movable frame on the carriage provided with a twister-head and a sprocket-wheel in position to engage with the vertical portion of the chain, and means for periodically locking the head and wheel against rotation and causing them to be moved from one horizontal wire of the frame to another.

20. The combination of a carriage provided with wheels and with guides; a sprocket-chain trained upon said wheels; means for driving said sprocket-chain; a traveling frame mounted upon the guides; a sprocket-wheel carried by the traveling frame and meshing with the sprocket-chain and provided with a catch for a pawl; a rotary twister mounted in the traveling frame and provided with a sprocket-wheel meshing with the sprocket-chain and also provided with oppositely-arranged radial slots to receive the horizontal strands of the frame; a spool-holder mounted on the twister at one side of the axis thereof; a pawl mounted in a traveling frame to engage the catch of the sprocket-wheel; a spring for holding the pawl in engagement with the sprocket-wheel; a belt for operating said pawl; a cam-disk for operating said belt; a slide mounted on the twister to register therewith and provided with slots on opposite sides of the twister to register respectively with the radial slots of the twister, the portion between said slots of the slide being of greater width than the portion of said slots of the twister, said said slide being arranged to engage the cam-disk to operate it in different directions.

21. In a woven-wire-frame machine, the combination of a traveling carriage; a twister-carrier arranged to move up and down in said carriage along the plane of the strands held by said twister; a rotary twister provided with means for carrying a wire at one side of the axis of said twister, said twister being arranged with slots on opposite sides of its axis; successive strands held by said twister; means for moving the twister in the plane of said strands; and means for rotating the twister to twist a wire around said strands, respectively, and to alternately bring one and the other of

the slots into position successively to receive the successive strands as the work proceeds.

22. In a woven-wire-frame machine, the combination with a traveling twister, of a sprocket-chain led around stationary wheels; a twister-carrier furnished with a twister; a sprocket-wheel engaging with the sprocket-chain for rotating said twister; a sprocket-wheel engaging with said chain for driving the twister-carrier; and means for holding a wire stationary in the path of said twister.

23. The combination of a twister-carrier consisting of two members a and b mounted upon guides and provided in their adjacent ends with bearings c and d ; a rotary twister provided with longitudinal grooves e and f and with an annular groove g into which the bearings c and d are adapted to slip the twister to hold it in the twister-carrier; a slide h arranged diametrically across the twister and provided with two members i and j to register with the longitudinal grooves e and f of the rotary twister and provided at its ends with shoulders k which limit the movement of the slide in the rotary twister; means for holding a wire in said twister; means for holding a wire around in the path of said twister; and means for rotating the twister around the strand.

700,711. **WIRE-SEPARATOR.** FRANKLIN E. WATSON, CHICAGO, ILL., assignor, by mesne assignments, of one-half to E. O. Malt and Robert J. Powell, Baltimore, Md. Filed May 8, 1901. Serial No. 68,957. (No model.)

Claim.—1. In an ore-separator, the combination with a casing, of a stop-flange located in the casing, and a rotating-roller carried by the flange and spaced from the inner face of the casing to form a holding-pocket, said roller being provided with an escape-opening.

2. In an ore-separator, the combination with a casing, of a stop-flange located in the casing, and a rotating-roller carried by the flange and spaced from the inner face of the casing to form a holding-pocket, said roller being provided with an inclined escape-opening.

3. In an ore-separator, the combination with a casing, of an annular stop-flange located in the casing, a rotating-roller carried by the flange and spaced from the inner face of the casing to form a holding-pocket, and wings carried by said rotating-roller and projecting into the pocket.

4. In an ore-separator, the combination with a casing, of an annular stop-flange located in the casing, a rotating-roller carried by the flange and spaced from the inner face of the casing to form a holding-pocket, said roller being provided with an escape-opening, and a wing carried by said rotating-roller, said wing being located contiguous to the escape-opening and projecting into the pocket.

5. In an ore-separator, the combination with a rotatable casing, of an annular stop-flange located in the casing, a rotating-roller carried by the flange and spaced from the inner face of the casing to form an annular pocket, said roller being provided with a plurality of inclined escape-openings, and inclined wings carried by the rotating-roller and arranged adjacent to the escape-openings, said wings projecting from both faces of the roller.

6. In an ore-separator, the combination with a rotatable casing, of an annular stop-flange located in the casing, a rotating-roller carried by the flange and spaced from the inner face of the casing to form an annular pocket, said roller being provided with a plurality of inclined escape-openings, and inclined wings carried by the rotating-roller and arranged adjacent to the escape-openings, said wings projecting from both faces of the roller.

7. In an ore-separator, the combination with an open-ended rotatable casing carrying journals at its ends, of an intermediate annular stop-flange arranged upon the interior of the casing, an annular rotating-roller carried by the stop-flange and spaced from the casing, said roller being provided with inclined escape-openings, inclined wings carried by the roller and projecting from both faces thereof, and other-ways located longitudinally upon the inner face of the casing and projecting into the space between the roller and the casing-wall.

8. In an ore-separator, the combination with an open-ended rotatable casing carrying journals at its ends, of an intermediate annular stop-flange arranged upon the interior of the casing, an annular rotating-roller carried by the stop-flange and spaced from the casing, said roller being provided with inclined escape-openings, inclined wings carried by the roller and projecting from both faces thereof, and other-ways

located longitudinally upon the inner face of the casing, and projecting into the space between the roller and the casing-wall.

9. In an ore-separator, the combination with a casing, of a stop-flange located in the casing, a rotating-roller carried by the flange and spaced from the inner face of the casing to form a pocket, said roller having a plurality of openings therethrough, a plurality of wings carried by the flange and disposed within the pocket, and a rib located longitudinally upon the inner face of the casing and having one end arranged within the pocket.

700,712. **MACHINE FOR JUSTIFYING TYPE.** JOHN WATSON, BROOKLYN, N. Y., assignor, by mesne assignments, to Edwin C. Hoyt and Felix Rosen, New York, N. Y. Filed June 20, 1901. Serial No. 68,958. (No model.)

Claim.—1. The combination of a rotating shaft driven from a suitable source of power; a cog-wheel on said shaft; an annular ring running loosely on said shaft, surrounding said cog-wheel; a pivoted dog controlled by a spring in the periphery of the ring, arranged to engage with the cog-wheel; a cam upon the shaft, engaging with a block upon the bar, arranged to hold the bar normally out of operation except when the block is moved off of the cam by the rotation of the shaft; mechanism, substantially as described, actuated by the foremost space-bar in the line-holder, for throwing the dog in and out of engagement at the proper instant; and means for preventing the mechanism from returning to normal position while each space-bar is being withdrawn from the line-holder.

2. The combination of a rotating shaft driven from a suitable source of power; a cog-wheel on said shaft; an annular ring running loosely on said shaft, surrounding said cog-wheel; a pivoted dog controlled by a spring in the periphery of the ring, arranged to engage with the cog-wheel; a cam upon the shaft, engaging with a block upon the bar, arranged to hold the bar normally out of operation except when the block is moved off of the cam by the rotation of the shaft; mechanism, substantially as described, actuated by the foremost space-bar in the line-holder, for throwing the dog in and out of engagement at the proper instant, and a cam-ring of suitable length, attached to the face of the cam along its periphery, for holding the end of the bar lever out of engagement with the connecting mechanism during a complete revolution of the cam.

700,718. **MACHINE FOR JUSTIFYING (SETUP) TYPE.** GEORGE F. WATSON and GEORGE H. WATSON, WASHINGTON, D. C., assignors of one-half to Wright and Collins Wire Cloth Company, Worcester, Mass., a corporation. Filed Jan. 5, 1901. Serial No. 68,959. (No model.)

Claim.—1. In a machine for covering coils of wire, the combination of means for supporting a coil of wire in a vertical position and on its lower edge, a fixed annular track for a rotating spool-carrier placed above said coil-support, said track having on its lower side a gap to receive the coil of wire with said gap in the vertical plane of said coil-support and a carrier adapted to rotate on said annular track, substantially as described.

2. In a machine for covering coils of wire, the combination of means for supporting a coil of wire in a vertical position and on its lower edge,

a fixed annular track for a rotating spool-carrier placed above said coil-support, said track having on its lower side a gap to receive the coil of wire, with said gap in the vertical plane of said coil-support and a carrier adapted to rotate on said annular track, said carrier having a gap to receive the coil of wire, means for rotating said carrier, and means for stopping said carrier with its gap corresponding with the gap in said track, substantially as described.

3. The combination of means for supporting and rotating the coil of wire to be covered, an annular carrier for carrying the covering material around the coil of wire, means for rotating said carrier, a stopper for controlling the rotation of said carrier, a projection on said carrier, and a movable stop arranged to be carried into the path of said projection synchronously with the movement of said stopper, substantially as described.

4. The combination of means for supporting and rotating the coil of wire to be covered, an annular carrier for carrying the covering material around the coil of wire, means for rotating said carrier, a projection on said carrier, and a movable stop arranged to be carried into the path of said projection, substantially as described.

5. The combination of means for supporting the coil of wire on its edge in an upright position, means for rotating the coil, a pair of rolls bearing against the sides of the coil near its upper edge to maintain it in an upright position, an annular track including one side of the coil, a carrier rotating in said track, and means for rotating said carrier, substantially as described.

6. The combination of means for supporting the coil of wire on its lower edge and in an upright position, means for rotating the coil, means for maintaining the coil in an upright position, an annular track including one side of the coil, a carrier rotating in said track, and means for rotating said carrier, substantially as described.

7. In a machine for covering coils of wire, the combination with a fixed annular track for a rotating carrier including the coil to be covered, a pair of rolls and a belt carried by said rolls and forming the support for the coil and means for raising and lowering said rolls to bring the inclined section of the coil concentric with said annular track, substantially as described.

8. In a machine for covering coils of wire, the combination with rotating covering mechanism, of a coil-support consisting of a pair of pulleys having parallel, horizontal axes, and a notched belt carried by said pulleys, said belt having a gripping upper surface whereby the notched edges of the belt engage the sides of the coil, substantially as described.

700,714. **RAILWAY-RAIL JOINT.** FRANK C. ANDERSON, CHICAGO, ILL., assignor of two-thirds to George W. Hoyt and Goodwin F. Hoyt, Chicago, Ill. Filed Mar. 13, 1901. Serial No. 68,960. (No model.)

Claim.—1. In railway-rail joints, the combination of the abutting ends of the rails, a low wedge-plate fitted to the under sides of said abutting ends of the rails, said low wedge-plate being beveled on its under side and thinned gradually toward its edges, fish-plates applied to each side of the abutting rails with their upper edges bearing against the under side of the head of the rail and having foot-plates of the same length as the fish-plate and base wedge-plate, said foot-plates bearing on the ap-

per side of the foot of the rail and extended around the outer edge thereof beneath the base wedge-plate and having their upper sides beveled to conform to the level of the wedge-plate, and clamping-bolts passed through said fish-plates and rails for uniting the parts, substantially as described.

2. In railway-rail joints, the combination of the shunting ends of the rails, a fish-plate applied to each side thereof with its upper edge bearing on the under side of the foot of the rail and having a footpiece bearing on the upper side of the foot of the rail and extended around the outer edge thereof to the under side with a beveled upper side, at its inner end, a base wedge-plate fitted to the under side of the foot of the rail with an upward flange at one side and having beveled under sides engaging the beveled sides of the under parts of the footpieces, and clamping-bolts passed through said fish-plates and rails for uniting the parts, substantially as described.

3. In railway-rail joints, the combination of the shunting ends of the rails, a fish-plate applied to each side thereof with its upper edge bearing on the under side of the foot of the rail and having a footpiece bearing on the upper side of the foot of the rail and extended around the outer edge thereof to the under side with a beveled upper side as its inner end, a base wedge-plate fitted to the under side of the foot of the rail with a downward corner to engage the lower side of the footpiece and having beveled under sides engaging the beveled sides of the under parts of the footpieces, and clamping-bolts passed through said fish-plates and rails for uniting the parts, substantially as described.

4. In railway-rail joints, the combination of the shunting ends of the rails, a fish-plate applied to each side thereof with its upper edge bearing on the under side of the foot of the rail and having a footpiece bearing on the upper side of the foot of the rail and extended around the outer edge thereof to the under side with a beveled upper side at its inner end, a base wedge-plate fitted to the under side of the foot of the rail with an upward flange at one side and with downward corners at the opposite side to engage the lower side of the footpiece and having beveled under sides engaging the beveled sides of the under parts of the footpieces, and clamping-bolts passed through said fish-plates and rails for uniting the parts, substantially as described.

5. In railway-rail joints, the combination of the shunting ends of the rails, a base wedge-plate fitted to the under sides of said shunting ends of the rails, said base wedge-plate being beveled on its under side and thinned gradually toward its edges, fish-plates applied to each side of the shunting rails with their upper edges beveled and bearing against the beveled under side of the foot of the rail and having footpieces of the same length as the fish-plates and base wedge-plates, said footpieces bearing on the upper side of the foot of the rail and extended around the outer edge thereof beneath the base wedge-plate and having their upper sides beveled to conform to the level of the wedge-plate all of said bevels having the same angle, and clamping-bolts passed through said fish-plates and rails for uniting the parts, substantially as described.

700,715. OPERATING MECHANISM FOR MOTOR-ELECTRICITY. JAMES I. AYER, Milton, Mass., assignor to the American Electric Company, Boston, Mass., a Corporation of Massachusetts. Filed Feb. 17, 1902. Serial No. 94,261. (No model.)

Claim.—1. In a device of the kind described, armature-control mechanism, field-control mechanism, means for locking said armature-control mechanism in short-circuit position, and means preventing the operation of said field-control mechanism until the armature-control mechanism has arrived at said short-circuit position.

2. In a device of the kind described, a rheostat, comprising a field-control lever and resistance therefor, an armature-control lever and resistance therefor, and means for positively moving the field-lever back to neutral position when the armature-lever is moved back to neutral position.

3. In a device of the kind described, armature-control mechanism, field-control mechanism, the latter requiring movement independent of the former for placing it in operative position, and a locking device for

locking the said two mechanisms together until the armature-control mechanism has been moved to short-circuit position.

4. In a device of the kind described, armature-control mechanism, field-control mechanism, the latter requiring movement independent of the former for placing it in operative position, a locking device for locking said two mechanisms together until the armature-control mechanism has been moved to short-circuit position, and means for then automatically unlatching said two mechanisms to permit said independent movement of said field-control mechanism.

5. In a device of the kind described, armature-control mechanism, field-control mechanism, means for locking said armature-control mechanism in short-circuit position, said field-control mechanism being operable independently of said armature-control mechanism when the latter is locked, and means controlled by the motor-circuit for automatically shifting said field-control mechanism and unlatching said lock upon interruption of said motor-circuit.

6. In a device of the kind described, field-control mechanism including a lever and a series of resistances, armature-control mechanism including a lever and a series of resistances, and means under the electrical control of the motor-circuit for automatically shifting said field-lever to cut out the field resistance before movement of the armature-lever.

7. In a device of the kind described, field-control mechanism including a lever and a series of resistances, armature-control mechanism including a lever and a series of resistances, means under the electrical control of the motor-circuit for automatically shifting said field-lever to cut out the field resistance before the movement of the armature-lever, and means cooperating therewith for withdrawing the field-lever and putting it into inoperative condition until the armature-lever has been put in short-circuit position for again starting the motor.

8. In a device of the kind described, a rheostat including field resistance, armature resistance, and independently-movable levers therefor, means for locking said two levers together excepting when the armature-lever is in its short-circuit position, and means for automatically unlatching said levers when the armature-lever is moved to its short-circuit position.

9. In a device of the kind described, an armature-control lever, resistance therefor, a spring-actuated device held under tension by the passage of current in the motor-circuit, a field-control lever, and resistance therefor included in a short field-winding, said field-control lever being located between said armature-control lever and said spring device, interruption of the remaining current of said spring-actuated device permitting the latter to shift said field-control lever for cutting out the field resistance before movement of the armature-control lever.

10. In a device of the kind described, resistance in a short field-winding, armature resistance, independent levers therefor coaxially mounted, and automatic means for shifting said levers, said shifting means engaging and shifting the field-control lever for cutting out its resistance, before engaging and starting the armature-control lever.

700,716. FEEDER. ALEXANDER BOW, Atlanta, Ga. Filed Sept. 18, 1901. Serial No. 75,508. (No model.)

Claim.—1. In a feeder, a wheel and means for mounting same rotatably on the front of the conveyance near the roadway, in combination with a conical apron above said wheel and in operative relation thereto.

2. In a feeder, a wheel provided with a hub abnormally long on one end, a conical apron secured by its lower edge to said wheel and by its upper end to said hub near its distal end and means for rotatably mounting said wheel on the front of the conveyance and just above the roadway.

700,717. HITCHING AND THERAGING LEVEL. RAYMOND A. BOWEN, Atlanta, Ga. Filed Feb. 12, 1901. Serial No. 57,008. (No model.)

Claim.—1. In a leveling instrument, a sighting-tube and means for leveling same, and a right-adjointing device consisting of a plate secured to one end of said tube, and a disk rotatably mounted on said plate having a series of holes therein at different radial distances adapted to register with said tube.

2. In a leveling instrument, a sighting-tube and means for leveling

same, and a right-adjointing device consisting of a plate secured to one end of said tube, and a disk rotatably mounted thereon having a series of holes therein at different radial distances and a hook adapted to engage said disk for locking the same.

3. In a leveling instrument, a sighting-tube and means for leveling same, and a right-adjointing device consisting of a plate secured to one end of said tube and a disk rotatably mounted on said plate and having a series of holes therein, at different radial distances, and means for locking same consisting of a spiral-spring coil having its end bent laterally into contact with and within said disk and a return-band projecting on the other side and adapted to engage the disk.

4. In a leveling instrument, a sighting-tube having a clevis end and its upper side, means for leveling said sighting-tube, on a smaller turret provided with parallel edges and fitting said end and having, at diametrically opposite points, apertures, one of which is elongated vertically, and a sighting-tube located in the aperture in said turret and adjusting-covers located in one of said apertures for the purpose of adjusting said tube.

700,718. MINING-CAR. DANIEL I. BOWEN, Birmingham, Ala., assignor of one-half to Arthur H. Brown, Birmingham, Ala. Filed Aug. 12, 1901. Serial No. 71,705. (No model.)

Claim.—1. In a mining-car, the combination of a body, substantially U-shaped cross-section to the body and provided with laterally-projecting spindles located above the plane of the bottom of the body, wheels mounted upon said axles, and spring-metal braces secured to the axles and provided with engaging members for detachable connection with the sides of the body, substantially as described.

2. In a mining-car, the combination of a body, axles supporting the body, wheels mounted upon said axles, and braces extending from the axles and detachably connected with the sides of the body to prevent swaying of said body, substantially as described.

3. In a mining-car, the combination of a body, axles supporting the body, wheels mounted upon said axles, and braces extending from the axles and having spring-chaps to engage the sides of the body to prevent swaying of said body, substantially as described.

REISSUES.

11,991. ELECTRIC-RAILWAY SYSTEM. GEORGE I. CAMPBELL, New York, N. Y., assignor to the International Electric Traction Company, New York, N. Y., a Corporation of West Virginia. Filed Mar. 27, 1891. Serial No. 68,128. Original No. 693,511, dated Aug. 31, 1896.

Claim.—1. In an electric-railway system, a conduit having a sectional main conductor, a trolley mounted to travel in said conduit in contact with said sectional conductor and carrying an armature arranged to be acted upon by the magnets of a moving car to cause the trolley to slide along the conduit, a sectional surface conductor separated from and external to said conduit and electrically connected with the sectional main conductor by the interior of the conduit, and a contact-piece on the car for contact with the said sectional surface conductor, substantially as shown and described.

2. In an electric-railway system, a conduit containing a main conductor consisting of two separated members, one of which is connected with a source of electricity and the other of which is external, a trolley mounted to travel on the two members of the said main conductor to electrically connect the members, a sectional surface conductor at one side of the said conduit and electrically connected with the external member of the main conductor and a contact-piece moving with the car and in engagement with the said sectional surface conductor, substantially as shown and described.

3. In an electric-railway system, a conduit having continuous and sectional main-conductor members, a trolley mounted to travel in said conduit in contact with said conductor members and carrying an armature arranged to be acted on by the magnets of a moving car, the said trolley being capable of opening up or falling in to establish or break connection with the members of the main conductor in the conduit when the trolley is under magnetic influence or not, a sectional surface conductor separated from and external to said conduit and electrically connected with the sectional main-conductor member in the interior of the conduit and a contact-piece on the car for contact with said surface conductor, substantially as shown and described.

4. In an electric-railway system, a closed conduit, if conductor connected with a source of electricity extending along the bottom of the conduit, a sectional conductor extending along the top of the conduit, a trolley mounted to travel in the conduit to connect the conductors at the top and bottom of the same, a sectional surface conductor external to and separated from said conduit and means to electrically connect the sections of said surface conductor with the sections of said sectional conductor at the top of the conduit.

5. In an electric-railway system, a conduit carrying a main conductor, a trolley mounted to travel therein and capable of opening up or falling in to establish or break connection with the members of the main conductor in the conduit when the trolley is under magnetic influence or not, and a trolley-support for the said trolley and thrown into action when the trolley falls up, to support the trolley in an upright position in the conduit, substantially as shown and described.

6. In an electric-railway system, a trolley capable of making connection between two conductors when the trolley is under magnetic influence and arranged to break connection between the conductors when the magnetic influence ceases, and means for supporting the trolley in its

upright position when connection between the conductors is broken, substantially as described.

7. In an electric-railway system, a trolley capable of making connection between two conductors when the trolley is under magnetic influence, and arranged to break connection between the conductors when the magnetic influence ceases, said trolley having members comprising two pivoted members connected with each other at or near their middle by a transverse pivot and adapted to open up or fold, substantially as set forth.

8. In an electric-railway system, a trolley capable of making connection between two conductors when the trolley is under magnetic influence, and arranged to break connection between the conductors when the magnetic influence ceases, said trolley having members pivotedly connected with each other to open or fold, and a trolley-support carried by one of the members, and adapted to be actuated by the other member when the members fold, to hold the trolley in an upright position.

9. In an electric-railway system, a conduct having internal conductors, a trolley mounted to travel in said conduct, said trolley having pivoted members adapted to open up to establish connection between said conductors and to fold up or close to break the connection between said conductors, and a support for the trolley furnished on the frame and moved into active position by the closing of the trolley members, substantially as shown and described.

10. In an electric-railway system, a conduct having internal conductors, a trolley mounted to travel in said conduct, said trolley having pivoted members adapted to open up to establish connection between said conductors and to fold up or close to break the connection between said conductors, and a support carried by one of the members, and adapted to be actuated by the other member on the closing of the trolley, to bring the support in engagement with the lower surface of the conduct, to support the trolley in an upright position when folded and out of engagement with one of the conductors, substantially as shown and described.

11. In an electric-railway system, a trolley comprising a frame having pivoted members, bottom and top wheels on said members, and an armature slidably mounted on said members, substantially as shown and described.

12. In an electric-railway system, a trolley comprising a frame having two members pivotedly connected with each other at or near their middle, wheels journaled on the ends of said members, and an armature carried by the upper portions of the members, substantially as shown and described.

13. In an electric-railway system, a trolley comprising a frame having two members pivotedly connected with each other at or near their middle, wheels journaled on the ends of said members, and an armature carried by the upper portions of the members, the armature having a sliding connection with said portions, substantially as shown and described.

14. In an electric-railway system, a trolley comprising a frame having two members pivotedly connected with each other at or near their middle, wheels journaled at the ends of the said members, and a support for the trolley carried by said frame, and adapted to be moved into an active position when the two pivoted frame members close, substantially as shown and described.

15. In an electric-railway system, a trolley comprising a frame having two members pivotedly connected with each other at or near their middle, wheels journaled at the ends of the said members, and a support for the trolley carried by said frame, and adapted to be moved into an active position when the two pivoted frame members close, said support consisting of levers pivoted to the lower portions of the frame members, and extending with one end into the path of the upper frame members, substantially as shown and described.

16. In an electric-railway system, a conduct carrying a conductor, a trolley arranged to travel in said conduct and comprising a frame having pivoted members free to swing into an open or closed position, and an armature for the magnets on the car, the said armature being carried by the upper portion of the members of the trolley-frame and having side flanges, substantially as described.

17. In an electric-railway system, a conduct containing a main conductor comprising upper and lower members, each having a longitudinal groove in its inner face, a trolley comprising a frame having pivoted members, bottom and top wheels on said members and adapted to travel in the groove in the conductor, and an armature carried by the members of the trolley-frame the said armature being formed on its top with a central portion fitting loosely in the groove of the upper member of the conductor, and also having side flanges extending to the sides of the said member of the conductor, whereby the armature presents a large top surface to the influence of the magnets on the car, substantially as described.

18. In an electric-railway system, a conduct carrying a conductor, a trolley arranged to travel in the conduct and having members pivotedly connected with each other to open or close, and a trolley-support consisting of levers furnished on the lower portions of the members to swing in a transverse direction, the upper or lower ends of said levers extending in the path

of the corresponding upper portion of the frame members and adapted to be engaged thereby to swing the levers outward when the frame members close, the outer or free ends of said levers being adapted to engage the sides of the conduct when the levers are swung outward, substantially as described.

11,999. CONVERTIBLE CAR. JOHN O'LEARY, Coburn, N. Y., assignor, by direct and license assignments, of Five-sixths to Le Roy Vermeulen, Coburn, N. Y. Filed Mar. 21, 1902. Serial No. 90,299. Original No. 694,993, dated Jan. 1, 1901.

Claim.—1. In a convertible car, the combination with the dashed roof, grooved roof-supporting ribs, and a series of inflexible slide-panels vertically movable in the rib-grooves; of a corresponding series of storage-chambers extending from one side of the car approximately to the top of the back of the car, substantially as described.

2. In a convertible car, the combination with a series of upwardly and inwardly inclined storage-chambers adjacent to the roof of the car; severally provided with oppositely-located apertures and inwardly inclined slideways; of a corresponding series of inflexible panels vertically movable in slideways in the vertical side walls of the car and severally provided with guides movable in the respective inclined chamber-slideways, substantially as described.

3. In a railway-car, the combination with a chamber extending from the raised deck to the side of the car; of a pair of ventilator-valves, one opening from the chamber through the upper side wall of the car exteriorly of the car, and the other opening from the chamber through the side wall of the deck interiorly of the car; and a connecting-link between the two valves, substantially as described.

4. In a convertible car, the combination with a pair of vertically-movable mutually-lapping panels; of a pair of panel-supporting ribs, each rib having, intermediate of its lower and upper ends, separate slideways for the respective panels, which slideways merge into each other and gradually increase in width and incline inwardly from the merging point toward the top of the car, substantially as described.

5. In a convertible car, the combination with a series of upwardly and inwardly inclined storage-chambers, adjacent to the car-roof; of a corresponding series of inflexible slide-panels each vertically movable in slideways gradually increasing in width from a point to the side wall of the car about midway of its top and bottom, to the mouth of the uppermost storage-chamber, where they correspond in width with such mouth, and a horizontal projection on the upper edge of a movable panel for closing the mouth of the chamber, substantially as described.

6. In a convertible car, having a dashed roof, the combination with an inclined dash-chamber extending upwardly and inwardly from the side of the car and provided at its outer and lower end with a downwardly-opening mouth, of a guideway extending in an irregular path from a point near the mouth of such chamber in close proximity to the outer and upper wall of such chamber approximately to the top of the deck; panel-supporting vertical ribs, and an approximately straight and inflexible panel provided with a guide on its upper end movable along said guideway, substantially as described.

7. In a convertible open and closed car, the combination of the sliding window casings and panels, one of said parts being formed with an abutment for the other to bear against and for maintaining one part from the other as they are raised, and means for supporting the casings and

panels in the space between the chamber-walls in the top of the car, substantially as described.

8. In a convertible open and closed car, the combination of the sliding window casings and panels, one of said parts being formed with an abutment for the other to bear against and for maintaining one part from the other when they are raised, and means for supporting the casings and panels in the space between the ceiling and roof of the car, substantially as described.

9. In a convertible open and closed car, the combination of the sliding window casings and panels, one of said parts being formed with an abutment having a recess to receive a portion of the other, so that the parts may be moved together and one be supported from the other when stored in the space between the ceiling and roof of the car, substantially as described.

10. In a convertible open and closed car, the combination of the sliding window casings and panels, members formed with ways to guide said parts when sliding; a plate or roller secured to one of said parts; and members formed with ways in the space between the ceiling and roof of the car to receive said plate and rollers for guiding said parts in said space, substantially as and for the purposes described.

11. In a convertible open and closed car, the combination of the sliding window casings and panels, means for maintaining said parts in a chamber in the upper part of the car; and ventilating-openings formed in the opposite walls of said chamber communicating respectively with the external atmosphere and with the interior of the car, and communicating with each other through said chamber, substantially as described.

12. In a convertible open and closed car, the combination of the sliding window casings and panels, means for maintaining said parts in the space between the ceiling and roof of the car, and ventilating-openings formed in the ceiling and in the portion of the car outside of said space and communicating with the space between the ceiling and roof, substantially as and for the purposes described.

13. In a convertible open and closed car, the combination with the car-body having a panel-receiving recess or chamber extending inwardly from the side wall of the car, and side ribs provided with panel supporting and guiding grooves leading to said chamber; of an inflexible panel; means for guiding said panel along the grooved ribs and into and out of said chamber; and means for supporting said panel in an inclined position in said chamber.

14. In a convertible open and closed car, the combination with the car-body having a panel-receiving recess or chamber extending inwardly from the side wall of the car, and side ribs provided with panel supporting and guiding grooves leading to said chamber; of a plurality of inflexible panels; means for guiding said panels along the grooved ribs and into and out of said chamber, and means for supporting said panels in inclined position, one above another, in said chamber.

15. In a convertible car, the combination with the car-body having open sides, and a plurality of posts extending vertically across the open sides, and severally provided with vertical slideways and adapted to close the several intervals between the posts, a chamber in the upper part of the car adapted to receive the panels when raised; and provided with ventilating-apertures in its walls, means for retracting and controlling the ventilation through such apertures; and a movable bottom for said chamber, substantially as described.

11,998. CUFF-HOLDER. WILLIAM THURMAN, Northport, Odo. Filed Apr. 9, 1902. Serial No. 148,126. Original No. 681,273, dated Aug. 27, 1901.

Claim.—A cuff-holder comprising a single piece of resilient wire bent to form a loop and diverging arms, the loop being offset from the plane of said arms, inwardly-projecting overlapping bands in said arms, constituting clamps to engage the shirt-sleeve, a loop at the end of one of said arms and a head at the end of the other arm for connecting said arms detachably.

DESIGNS.

85,916. POCKET-TIME OR SIMILAR ARTICLE. GEORGE A. KESTY-SUMMIT, Newark, N. J. Filed Jan. 26, 1902. Serial No. 91,299. Term of patent 7 years.

Claim.—The design for a pocket-piece or similar article substantially as shown and described.

85,917. CARD PLATE OR HOLDER. ORLANDO A. BROWNE, New York, N. Y., assignor to Standard Furniture Company, New York, N. Y., a Corporation of New York. Filed Mar. 20, 1902. Serial No. 100,000. Term of patent 14 years.

Claim.—The design for a card plate or holder, substantially as shown and described.

85,918. GLASS BOWL. EDWARD J. Egan, Chicago, Ill. Filed Apr. 20, 1902. Serial No. 104,596. Term of patent 24 years.

85,918.

Claim.—The design for a glass dish, substantially as herein shown and described.

85,919. WIRE FENCE. JAMES F. BARNES, Fort Worth, Tex. Filed Jan. 21, 1902. Serial No. 80,750. Term of patent 14 years.

Claim.—The design for a wire fence, as herein described and illustrated in the accompanying drawing.

85,920. GAMING FIVE HOLDING COATS, UMBRELLAS, OR ALBERT A. HOLMES, Marshall, Mich. Filed Dec. 12, 1901. Serial No. 80,751. Term of patent 7 years.

Claim.—The design for a gaming five holding coats, umbrellas, or albert a. holmes, Marshall, Mich., substantially as shown and described.

85,921. LACE CURTAIN. ARTHUR BROWN, Philadelphia, Pa., assignor to Joseph H. Brown, Philadelphia, Pa. Filed Apr. 14, 1902. Serial No. 100,000. Term of patent 7 years.

Claim.—The design for a lace curtain, substantially as shown and described.

TRADE-MARKS

REGISTERED MAY 20, 1902.

88,385. TRANSPARENT WRAPPING-PAPER. HENRY LAMON, NEW YORK, N. Y. Filed Apr. 3, 1902.

JAPANIN

The word "JAPANIN." Used since October 15, 1896.

88,386. BOTTLE-CAP. HENRY LAMON, NEW YORK, N. Y. Filed Apr. 14, 1902.

The letters and character "H & L" and a surrounding diamond-shaped figure. Used since February 1, 1901.

88,387. CERTAIN MARKED FIVE SOON. GEORGE A. FROST, St. Paul, Minn. Filed Dec. 21, 1901.

The representation of a shield upon a background of fur, having upon its face a Greek cross with diagonal cross-lines and the symbol "G & F" above it, and a scroll of conventionalized foliage ornamented by a small wolf-like animal, at each side a bear in standing position, and below it a scroll. Used since September 1, 1901.

88,388. CERTAIN MARKED FIVE SOON. LAUREL COTTON MANUFACTURING CO., Lowell, Mass. Filed Dec. 12, 1901.

The conventional representation of a Chinese sun surrounded by a border. Used since September, 1901.

88,389. CERTAIN MARKED FIVE SOON. ARTHUR OTTO MEYER, Hamburg, Germany. Filed June 12, 1901.

The representation of a horrible sun of Chinese type holding a globe with one paw and flanked at either side by a palm-tree. Used since August 11, 1900.

88,390. CERTAIN MARKED FIVE SOON. ARTHUR OTTO MEYER, Hamburg, Germany. Filed June 12, 1901.

The representation of a water-buffalo enclosed by a shield-like border. Used since April 20, 1901.

88,391. WOOL, COTTON, HALF-WOOL, SILK, AND HALF-SILK FABRICS EXCEPT SILK VELVETS, AND COTTON, WOOL, AND SILK THREADS AND FIBERS. ARTHUR OTTO MEYER, Hamburg, Germany. Filed June 12, 1901.

The representation of an ornamented key arranged in the center of a horrible shield. Used since May 6, 1905.

88,292. CERTAIN HAIRED EYE BOWNS. ARTHUR OTTO MEYER. Hamburg, Germany. Filed June 12, 1901.

The representation of an anchor, on the cross-bar of which are seated two parrots facing each other. Used since February 8, 1895.

88,298. COTTON FABRIC. WARD, HANBURY & Co., London, England. Filed Mar. 4, 1902.

The representation of the head of a rhinoceros arranged above a shield divided into two fields, the upper one displaying a sunburst and the lower one downward-projecting flames, the whole being arranged above a ribbon displaying the motto "POST HOC PROPTER HOC." Used since March, 1898.

88,294. BOOTS AND SHOES. HANCO, BROTHERS & Co., Marshall, Minn. Filed Apr. 14, 1902.

THE UTILITY

The words "THE UTILITY." Used since April 5, 1902.

88,295. BOOTS AND SHOES. WILSON & WHITEHEAD, Campbell, Mass. Filed Apr. 7, 1902.

Waukerz

The word "WAUKERZ." Used since 1887.

88,286. LIQUID KEMERY FOR THE CURE OF FILM. CHARLES A. FURBER, Boston, Mass. Filed Jan. 4, 1902.

The letters "C A P" arranged in monogram form. Used since January 1, 1900.

88,297. MEDICATED TABLETS FOR THE CURE OF CERTAIN NAMED DISEASES. JAMES D. CLARK, Pueblo, Colo. Filed Mar. 2, 1902.

Lithron

The word "LITHRON." Used since June, 1899.

88,298. TOILET ORANGE OINTMENTS AND SOAP. IRVING A. HOLMES & Co., Brooklyn, Mich. Filed Mar. 21, 1902.

LANAZOIN

The word "LANAZOIN." Used since July 10, 1901.

88,299. ANTISEPTIC. SOCIÉTÉ ANONYME DES PRODUITS CHIMIQUES INDUSTRIELS, Lyons, France. Filed Oct. 30, 1901.

HERMOPHENYL

The word "HERMOPHENYL." Used since March 18, 1901.

88,300. GELATIN AND PREPARATIONS OF GELATIN. MILLIGAN & HIGGINS GUM CO., New York, N. Y. Filed Apr. 3, 1902.

WHITE-FROST

The words "WHITE FROST." Used since March 7, 1902.

88,301. MINERAL WATER. WINDOL MINERAL WATER COMPANY, Indianapolis and Warsaw, Ind. Filed Feb. 28, 1902.

The word "WINDOL" and a medallion bearing the representation of the head and shoulders of an Indian maiden, surrounded by a landscape scene comprising rocks and trees with wigwags in the background. Used since June, 1901.

88,302. BREAKFAST-FOOD, CRACKERS, AND BISCUITS. GARDNER'S BREAD CO., Lansing, Michigan. Filed Apr. 21, 1902.

EAT-A-BISCUIT

The hyphenated word "EAT-A-BISCUIT." Used since February 25, 1902.

88,303. WHEAT-FLOUR. FRANKLIN & ATTENSON, Minneapolis, Minn. Filed Apr. 2, 1902.

PAUL REVERE

The words "PAUL REVERE." Used since February 21, 1902.

88,304. SOAP. NEW ORLEANS SOAP CO., LANSING, New Orleans, La. Filed Feb. 14, 1902.

The words "WHITE RABBIT" and the representation of a white rabbit. Used since January 24, 1902.

88,305. SOAP. NEW ORLEANS SOAP CO., LANSING, New Orleans, La. Filed Mar. 26, 1902.

The representation of a rabbit. Used since January 29, 1902.

88,306. LAUNDRY SOAP. HENRIKSON SOAP WORKS, Detroit, Mich. Filed Aug. 17, 1901.

The pictorial representation of the landing of Odette, as represented by an ancient statue containing the landing party, with the figure of Odette conspicuously shown standing in the bow, together with the flag of Louis XIV displayed over his head. Used since July 22, 1901.

88,307. CORN-OIL AND CORN-OIL CAKE. NATIONAL BRAND COMPANY, New York, N. Y. Filed Apr. 28, 1902.

The word "DIAMOND" and the representation of a diamond-shaped figure. Used since 1897.

88,308. PETROLEUM LUBRICATING AND LUBRICATING OILS. THE OILS COMPANY, New York, N. Y. Filed Apr. 10, 1902.

Mail-Coat

The monogram "QW" accompanied with the compound word "MAIL-COAT." Used since May 27, 1901.

88,309. CERTAIN HAIRED VARIETIES. GARDNER'S BREAD CO., Lansing, Michigan. Filed Mar. 14, 1902.

KISMET

The word "KISMET." Used since January 1, 1902.

88,310. THERMOMETER, JOURNAL GLASSWARE AND INSTRUMENTS. BROWN, DUNSTON & CO., New York, N. Y. Filed Apr. 14, 1902.

KOHINOOR

The word "KOHINOOR." Used since March 15, 1902.

88,811. **UWANTA.** STRASSER & CO., New York, N. Y. Filed Apr. 18, 1902.

Uwanta.

The word "UWANTA." Used since March 10, 1902.

88,812. **CHINA AND BARTHELEMY.** ARNOLD Goss Meyer, Hamburg, Germany. Filed June 12, 1902.

The representation of a palm-tree and an anchor placed across the trunk of the tree. Used since June 5, 1902.

88,813. **SHARKEN WARE.** A. GROSS, HAWAIIAN COMPANY, St. Louis, Mo. Filed Apr. 7, 1902.

A Maltese cross, in the center of which is a red circular figure. Used since January 1, 1901.

88,814. **CERTAIN NAMED OUTLINE.** DANIEL FRANK, Cologne, Germany. Filed Dec. 24, 1901.

The representation of a barrel. Used since July, 1900.

88,815. **CERTAIN NAMED RED-BOTTOMS AND BOTTLE.** THE NATIONAL SPRING BED-COMPANY, New-Britain, Conn. Filed Apr. 12, 1902.

RIP VAN WINKLE.

The word "RIP VAN WINKLE." Used since February, 1902.

THE MORRIS PETERS CO., PHOTO-LITHO., WASHINGTON, D. C.

88,816. **LORD DERBY.** THE CHURCHMAN & CO., Omaha, Neb. Filed Apr. 7, 1902.

LORD DERBY

The word "LORD DERBY." Used since January 1, 1902.

88,817. **VERMILION.** NEW YORK BROWN & FLEMING CO., Ltd., New York, N. Y. Filed Jan. 12, 1902.

The representation of a crown-shaped view of a bottle-top where the fastenings are embedded, having thereon a clock-dial and the word "ON TIME TO THE MINUTE." Used since July 1, 1901.

88,818. **MOVING-MACHINE.** BARNES PATENT COMPANY, Chicago, Ill. Filed Apr. 12, 1902.

The representation of a detached half-section of a cutter-bar, seen from the top, and which has the two diverging ribs on the upper surface toward the center thereof and substantially parallel to the beveled cutting edges of the half-section. Used since February, 1902.

88,819. **RAVING-SULLEY PERILLA.** BARNES & COMPANY, New York, N. Y. Filed Dec. 24, 1901.

R-B-S

The letters "R-B-S." Used since June 1, 1901.

88,820. **WINE.** GROSS & COMPANY, Stockholm, Sweden. Filed Feb. 11, 1902.

The representation of a peninsula as a wave-line, from which small slender-balls are projected. Used since January 21, 1901.

DECISIONS

OF THE
COMMISSIONER OF PATENTS
AND OF
UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

FREDERICK C. FREDERICK AND FREDERICK.

Decided April 26, 1902.

1. INTERFERENCE—MOTION TO DISOLVE—NON-COMPLIANCE WITH RULES.

A motion to dissolve an interference brought after testimony has been taken and unaccompanied by a motion to transmit to the Primary Examiner and by no excuse for the delay is not brought in accordance with the rules and has no standing.

2. SAME—SAME—JOINT APPLICATION AND SOLE APPLICATION OF ONE OF JOINT APPLICANTS.

When an interference is declared between a joint application and a sole application of one of the joint applicants, the question of priority necessarily resolves itself into a determination as to whether the entity composed of the joint applicants ever made the invention at all. A motion to dissolve, therefore, which sets up as a reason for dissolution that the record shows that the joint applicants never made the invention is irregular, since it seeks to obtain a decision on the very question which is to be decided at final hearing.

On petition.

IT IS THE ORDER OF THE COMMISSIONER

Application of Alonso D. Frederick filed July 3, 1901, No. 31,334. Application of John C. and Alonso D. Frederick filed December 11, 1900, No. 30,578.

Mr. Thomas G. Orwig for Alonso D. Frederick.
Mr. J. R. Nottingham for John C. and Alonso D. Frederick.

ALLEN, Commissioner:

This is a petition from a decision of the Examiner of Interferences denying a motion to dissolve the above-entitled interference. The petitioner requests that—

* * * the Examiner be instructed to the effect that the motion has standing and should be heard upon its merits notwithstanding all the objections he has made to it.

It appears that this interference was declared between the joint application of Frederick and Frederick and the sole application of A. D. Frederick, one of the joint applicants. The preliminary statements were approved October 12, 1901. Testimony was taken by the respective parties and final hearing was set for March 24, 1902. On March 6, 1902, the motion to dissolve was filed by A. D. Frederick, the sole applicant. This motion was brought in view of certain facts appearing in the preliminary statements of the parties and in the answer by

J. C. Frederick in his response to cross-question 20, which facts, it is alleged, tend to prove that the invention was made by A. D. Frederick alone and that it is not a joint invention made by Frederick and Frederick.

The Examiner of Interferences held that the motion had no standing and denied the same. Thereupon the present petition was taken by A. D. Frederick.

It is clear from this statement of the facts appearing in the record that the motion to dissolve is, in effect, a motion based upon the ground that the party Frederick and Frederick has no right to make the claim in issue, and the alleged bar is created upon the disclosure in the interference proceedings.

Rule 123 provides that motions which deny a party's right to make the claim should be made, if possible, within twenty days after the approval of the preliminary statements and that they should be accompanied by a motion to transmit the same to the Primary Examiner. When motions to dissolve are filed outside this limit, a showing in excuse of the delay should be filed therewith.

Petitioner has complied with none of these requirements. Not only was his motion filed long after the period fixed by the rule had expired, but there was no motion to transmit filed therewith; nor was any excuse given for not presenting the motion earlier. Upon these grounds alone the holding that the motion has no standing was proper. It appears, however, that the motion is based upon matters arising out of the interference proceedings and sets up as a reason for dissolution that the record shows that Frederick and Frederick are not, in fact, joint inventors. In other words, this motion seeks to obtain a decision on the very question which is to be decided upon final hearing, for in an interference of this kind between an application of joint inventors and a sole application of one of them the question of priority necessarily resolves itself into a determination as to whether the entity composed of the joint applicants had ever made the invention at all. (*Kohler v. Kohler and Chambers*, 48 O. G., 247.) It is the purpose of such an interference proceeding to develop the facts and the truth as to this point. The decision

in a case of this kind should be made in the regular way and not in the way proposed by petitioner. The decision of the Examiner of Interferences that the motion to dissolve has no standing was correct, and it is accordingly affirmed.

EX PARTE LANDENBERGER.

Decided May 15, 1902.

RETURN OF FEE—ERROR IN JUDGMENT—CAVEAT.

Where a caveat is filed which fails to clearly disclose the invention, Held that the fee will not be returned as paid by mistake. An error in judgment does not warrant the return of a fee.

ON petition.

FOUNT-BAR FOR LACE-KNITTING MACHINES.

Caveat of Gustav A. Landenberger filed March 20, 1902.

Mr. Ed. A. Kelly for the applicant.

ALLEN, Commissioner.

This is a petition that the filing fee paid in the above-entitled case be returned under the provisions of Rule 300 on the ground that it was paid by mistake. It appears from the record that after this caveat was filed the Examiner wrote a letter stating that the disclosure therein was insufficient to satisfy the provisions of Rule 188 and was not sufficiently clear to enable the Office to determine whether notice should be given the caveator in case of an interfering application. He further said:

The caveator should illustrate the application of his device to the existing machine which he seeks to improve, and he should fully describe its operation; or if he is not able at this time to describe the operation he should describe the manner in which he is seeking to accomplish the particular function which he has conceived for his apparatus.

Instead of complying with this requirement the caveator filed this petition for a return of the fee. He states that he believed that a statement of the broad purpose of his invention was sufficient to entitle him to notice of any application having in view the same broad purpose and that therefore the caveat was filed and the fee paid by mistake. He states, further, that he is unable to furnish the description of the invention as suggested and that he wishes to file an application as soon as his invention is completed.

It is apparent that the mistake, if any, was as to the effect which the caveat would have when filed. The rules set forth the requirements as to caveats, and in every case the inventor must determine for himself whether his ideas are sufficiently matured to enable him to convey a clear idea of the invention to others by a written description. It must be apparent to every one that a caveat which does not convey any certain idea of the invention is ineffective. If the applicant in this case has made a mistake, it is one of judgment in supposing that the caveat would disclose his ideas so that they could be understood. Such mistakes do not come within the provisions of the statute and Rule 300 relating to the return of money. (See *ex parte Ayres*, 51 O. G., 1944; *ex parte Hallberg*, 88 O. G., 1306; *ex parte Arakellon*, 85 O. G., 1077.)

The petition is denied.

[Vol. 99, No. 8.]

DECISIONS OF THE U. S. COURTS.

Supreme Court of the United States.

THE CARNEGIE STEEL COMPANY, LIMITED, v. THE CAMBRIA IRON COMPANY.

Decided May 5, 1902.

1. PATENTS—JONES—MIXING PIG METAL—VALID AND INFRINGED. Letters Patent No. 404,414, granted to William R. Jones on June 4, 1889, for a method of mixing molten pig metal, Held valid and infringed. (Decision below, 98 F. R., 880, reversed.)

2. PROCESS—ANTICIPATION—ONE STEP NEW.

Where the patentee's process of mixing molten metal drawn from several blast-furnaces includes retaining at all times a substantial quantity of molten metal in the mixer and this step is what adds value to the process and makes it a success, Held not anticipated by mixing devices in which the metal might be retained when the users did not contemplate such use or understand its advantage.

3. SAME—SAME—SAME—RESULT LONG SOUGHT FOR.

Where the manufacturers of steel had spent years in endeavoring to find out a process for accomplishing the results of this invention which is but a step from what they already knew, it is surprising with the wisdom which comes after the fact that they did not discover it.

4. SAME—SAME—PROCESS NOT ANTICIPATED BY APPARATUS.

To anticipate a process patent it is necessary not only to show that the prior patent might have been used to carry out the process, but that such use was contemplated or that it would have occurred to an ordinary mechanic in operating the device.

5. SAME—SAME—APPARATUS AND PROCESS DISTINGUISHED.

A mechanical patent is anticipated by a prior device of like construction and capable of performing the same function, but it is otherwise with a process patent. A process patent can only be anticipated by a similar process.

6. SAME—SAME—FUNCTION OF MACHINE.

If a process is the mere function of a machine, another machine capable of performing the same function might be an anticipation; but this is not because a process can be anticipated by a mechanism, but because the mere function of a machine is not patentable as a process at all.

7. CONSTRUCTION OF CLAIM—SPECIFICATION CONSIDERED—CLAIM BROAD IN THREE.

The second claim apparently extends to the art of mixing all molten metals; but the claim of a patent must always be explained by and read in connection with the specification, and when so considered this claim clearly includes metal from blast-furnaces. It is not rendered void by the possibility of its including cupola metal.

8. SUFFICIENCY OF DESCRIPTION—PATENT ADDRESSED TO THOSE SKILLED IN THE ART.

The specification of the patent is not addressed to lawyers or even to the public generally, but to the manufacturers of steel, and any description which is sufficient to apprise them in the language of the art of the definite feature of the invention and to serve as a warning to others of what the patent claims as a monopoly is sufficiently definite to sustain the patent.

9. SAME—NEED NOT DESCRIBE WHAT IS OLD IN THE ART.

A patentee in describing his invention may assume that what is already known in the art is understood and may begin at the point where his invention begins and describe what he has made that is new and what it replaces of the old.

10. DISCLAIMERS—PROPERLY ADMITTED AFTER ARGUMENT.

Where after the argument the plaintiff was permitted to file a disclaimer to certain statements in the specification which were broader than the claims when construed as contended for, Held that the admission of the disclaimer was proper.

11. SAME—MAY REFER TO SPECIFICATION AS WELL AS CLAIM.

The power to disclaim is a beneficial one and ought not to be denied except when it is resorted to for a fraudulent and deceptive purpose. A disclaimer may extend to a part of the specification as well as to a claim.

12. SAME—CANNOT CHANGE INVENTION CLAIMED—REMARK.

A disclaimer the purpose of which is to reform or alter the description of the invention or convert the claim for one thing into something else is objectionable, since patents can only be amended for mistakes of this kind by a referee.

13. STIPULATION—CONTRARY TO EVIDENCE—NOT BINDING AFTER NOTICE.

Where a stipulation was signed to the effect that the amount of molten metal in the defendant's mixer varies from nothing to its full capacity, but upon the facts being more fully ascertained notice was given by the plaintiff that the stipulation in so far as it was contrary to the evidence would be repudiated, Held that the stipulation is not binding.

14. SAME—MAY BE REPUDIATED UPON PROPER NOTICE.

While a stipulation is undoubtedly admissible in evidence, it ought not to be used as a pifall, and where the facts subsequently developed show with respect to a particular matter that it was inadvertently signed counsel may upon giving notice in sufficient time to prevent prejudice to the opposite party repudiate any fact inadvertently incorporated therein.

ON writ of certiorari to the United States Circuit Court of Appeals for the Third Circuit.

STATEMENT OF THE CASE.

This was a bill in equity filed in the Circuit Court for the Western District of Pennsylvania by the Carnegie Steel Company against the Cambria Iron Company, for an injunction and the recovery of damages for the infringement of Letters Patent No. 404,414, issued June 4, 1889, to William R. Jones, of whom plaintiff was the assignee, for a "method of mixing molten pig metal."

In his specification the patentee declares that the—

primary object of my invention is to provide means for refining the product of steel works uniform in chemical composition. In practice it is found that metal tapped from different blast-furnaces is apt to vary considerably in chemical composition, particularly in silicon and sulfur, and such lack of uniformity is observable in different portions of the same cast, and even in different portions of the same pig. . . . The consequence of this tendency of the silicon and sulfur to segregate or form pockets in the crude metal is that the product of the refining process in the converters or otherwise in like manner lacks uniformity in these elements, and therefore often causes great inconvenience and loss, making it impossible to manufacture all the articles of a single order of homogeneous composition. Especially is this so in the process of refining crude iron ladles from the smelting-furnaces and charged directly into the converter without remelting in a cupola, and, although such direct process possesses many economic advantages, it has on this account been little practiced.

For the purpose of avoiding the practical evils above stated, I use in the refining process a charge composed not merely of metal taken at one time from the smelting-furnaces, but of a number of parts taken from different smelting-furnaces, or from the same furnace at different casts, or at different periods of the same cast, and subject the metal before its final refining to a process of mixing, whereby its particles are diffused or mingled thoroughly among each other, and the entire charge is practically homogeneous in composition, representing in each part the average of the unequally diffused and segregated elements of silicon and sulfur originally contained in each of the several parts or charges. By proceeding in this way not only is each charge for the refining-furnace or converter homogeneous in itself, but, as it represents an average of a variety of uniform constituent parts, all the charges of the converter from time to time will be substantially uniform, and the products of all will be homogeneous.

To this end my invention may be practiced with a variety of forms of apparatus—for example, by merely receiving in a charging-ladle a number of small portions of metal taken from several ladles or receiving vessels containing crude metal obtained at different times or from different furnaces, the mixing being performed merely by the act of pouring into the charging-ladle, and other like vessels may be employed. (The claims in this case were subsequently disclaimed.) I prefer, however, to employ the apparatus shown in the accompanying drawings, and have made it the subject of a separate patent application, Serial No. 281,078, and, without intending to limit the invention to the use of that specific apparatus, I shall describe it particularly, so that those skilled in the art may intelligently employ the same. My invention is not limited to its use in connection with converters, since similar advantages may be obtained by casting the metal from the melting vessel into pigs for use in converters, puddling-furnaces, or for any other use to which pig-iron may be put in the art. (This paragraph subsequently disclaimed.)

(The apparatus is represented by the drawing here inserted.)

[Vol. 99, No. 8.]

Referring now to the drawings, 2 represents the reservoir here mentioned. It consists of a covered hollow vessel having an outer casing 3, of iron or steel, which is suitably braced and strengthened by interior beams and tie-rods, as shown in the drawings. The whole exterior of the vessel is lined with fire-brick or other refractory lining, which should be of sufficient thickness to retain the heat of the molten contents of the vessel and to prevent chilling thereof. The vessel is strongly braced and supported by braces and tie-rods, and may be of any convenient size, holding, say, one hundred tons of metal, (more or less,) and its shape is preferably such as shown in the drawings, being rectangular, or nearly so, in cross-section and an irregular trapezium in longitudinal section, one end being considerably deeper than the other. At the top of the deeper end, which I call the "rear" end, is a hopper 4, into which the molten metal employed in charging the vessel is poured, and as the front end is a discharge-spout 5, which is so located that the bottom of the spout is some distance above the bottom of the vessel—any two feet in a hundred-ton tank, and more or less, according to the capacity of the vessel—the purpose of which is that when the metal is poured out of the spout a considerable quantity may always be left remaining and unpoised, and that whenever the vessel is replenished there may already be contained in it a body of molten metal with which the fresh addition may mix. I thus secure, as much as possible, uniformity in character of the metal which is fed to and discharged from the tank, and cause the fluidity and quality of the successive tapplings to be very gradual.

For convenient use of the apparatus I have found it best to so arrange it that it be adapted to receive its charges of metals from cars or bogies 7, which run on an elevated track at about the level of the normal position of the hopper 4, and to discharge its contents into similar cars or bogies 8 on a track below the spout 4. In order to facilitate the charging and discharging of the metal, the vessel is put on journals or bearings 9, which have their bearings in suitable pedestals 10, and its rear end is provided with descending rock-holes 11, which are pivotedly connected with the bottom of the mixing vessel 2 and are in gear with pinions 12, the shaft of which is connected by a suitable engine 13 with the driving mechanism of a suitable engine. The pinions are held in gear with the rock-holes by idler wheels or rollers 14. As the journals or bearings are located on a transverse line somewhat in advance of the center of gravity of the vessel, it tends by its own weight to tilt backward into the position shown in Fig. 1, but may be returned to a level position by driving the pinions 12, and thus raising the rock-holes 11 until the front part of the bottom of the vessel comes in contact with a rest or stop 15.

The mode of operation of the apparatus is as follows: When the vessel is in the backwardly-tilted position shown in Fig. 1, it is ready to receive a charge of metal from the car 7. Before introducing the first charge, however, the mixing vessel should be heated by internal combustion of coke or gas, and

when the walls of the vessel are sufficiently hot to hold the molten metal without chilling it it is charged repeatedly from the cars 7 with metal obtained either from a number of furnaces or at different times from a single furnace. The charges of metal introduced at different times into the vessel, though differing in quality, mix together, and when the vessel has received a sufficient charge its contents constitute a homogeneous molten mass, whose quality may not be precisely the same as that of any one of its constituent charges, but represents the average quality of all the charges. If desired, the commingling of the contents may be aided by stirring or shaking of its liquid contents. The molten chamber being deeper at its rear than at the front end, as before described, and its normal position when not discharging metal for the purpose of casting being with the bottom inclined upward toward the front or discharging end, and the bottom of the spout being situated above the bottom of the vessel at its forward end, it is adapted to receive and hold a large quantity of molten metal without its surface rising high enough to enter the discharge-spout.

The discharge-spout 5 is furnished with a movable cover operated by a weighted lever 11, which, when closed, serves to exclude the outside air and prevent a draft of air through the vessel and the consequent rapid cooling of the molten contents. If care is exercised in lowering the cover closed, the metal can be kept in a fluid condition for a long time, the heat being kept up by repeated fresh charges of molten metal, and, if necessary or found desirable, by burning gas introduced by a pipe or pipes into its interior.

After the vessel is properly charged, the metal is drawn off into the cars 15 from time to time, as it is needed, by opening the door or cover 18 of the spout 5 and driving the engine 12, so as to elevate the rear end of the vessel and tilt it forward, and thus to discharge any required amount of its contents in the manner before explained into the cars 15, which are transported to the converters, or the metal is cast into pigs or otherwise used. (Italics disclaimed.) The tilting of the vessel does not, however, drain off all the contents thereof, a portion being prevented from escaping by reason of the elevated position of the spout 5, and as the vessel is replenished from time to time each new charge mixes with parts of previous charges remaining in the vessel, by which means any sudden variations in the quality of the metal supplied to the converter is avoided. Instead of discharging the metal into the cars 15 and carrying it in the cars to the converters or casting-house, the vessel 2 may be so situated relatively to the other parts of a furnace plant as to deliver its contents immediately to the converters or other place where it is to be utilized. I find it in practice very advantageous to employ two or more mixing vessels constructed substantially as I have described, and to draw a portion of each converter charge from each of the mixing vessels. My invention is, however, not limited to the employment of two or any specific number of such vessels.

I shall now describe, briefly, other parts of the apparatus which are desirable and important in its practical use.

At the top of the vessel 2 are manholes 17, designed to permit of access to its interior for the purpose of repairing or fixing the lining. These holes are provided with suitable covers 18 to exclude cold drafts of air from entering the interior. There is also a hole 19 at the rear end of the vessel near the top, through which a rammer may be inserted for the purpose of assisting or accelerating the melting of the molten metal, and at the other end, at the level of the bottom of the interior, there are holes 20, provided with suitable spouts to enable all the molten contents to be drawn off when it becomes necessary to do so. (See Fig. 1.) The holes 20 should be provided with suitable stoppers.

I claim—
1. In the art of refining iron directly from the smelting-furnace, the process of equalizing the chemical composition of the crude metal by thoroughly commingling or mixing together the liquid-metal charge and subsequently refining the mixed and equalized charge, substantially as and for the purposes described.

2. In the art of mixing molten metal to secure uniformity of the same in its constituent parts preparatory to further treatment, the process of introducing into a mixing-receptacle successive portions of molten metal of uniform or their non-metallic constituents, (sulfur, silicon, &c.) removing portions only of the composite molten contents of the receptacle without entirely draining or emptying the same, and successively replenishing the receptacle with fresh uniform additions, substantially as and for the purposes described.

The answer set up the invalidity of the patent by reason of an insufficient specification, anticipation, want of novelty and abandonment, and also denied infringement.

Upon a hearing upon the pleadings and proofs, the circuit court held with the plaintiff, and found that the process was patentable; that it was not anticipated; that it was of great utility and importance, and that defendant had infringed the second claim. (89 Fed. Rep., 731.)

A decree having been entered for an injunction and an account of profits and damages, in accordance with this opinion, the case was carried to the court of appeals, which ordered the decree of the circuit court to be reversed, and the case remanded to that court with direction to dismiss the bill. (96 Fed. Rep., 850.) Whereupon plaintiff applied for and was granted this writ of certiorari.

[Vol. 99. No. 9.]

Mr. Thomas B. Reed, Mr. P. C. Knox, Mr. T. B. Kerr, and Mr. T. W. Bakewell for the petitioner.
Mr. James I. Kay, Mr. P. T. Dodge, and Mr. F. T. Chambers for the respondent.

Mr. JUSTICE BROWN delivered the opinion of the Court.

Steel is a product, or, perhaps, more accurately, a species of iron, refined of some of its grosser elements, intermediate in the amount of its carbon between wrought and cast iron, and tempered to a hardness which enables it to take a cutting edge, a toughness sufficient to bear a heavy strain, an elasticity which adapts it for springs and other articles requiring resiliency, as well as a susceptibility to polish, which makes it useful for ornamental and artistic purposes.

Pig-iron, which was the original basis for the manufacture of all iron and steel, is made by the reduction of iron ore in large blast-furnaces, which are filled with layers of ore, charcoal or coke and flux. By the agency of this the iron is melted out and falls to the bottom of the furnaces, is drawn out through openings for that purpose into canals, and finally into molds, where it solidifies into what are termed pigs. Prior to the invention of Sir Henry Bessemer, steel was manufactured from a pig-iron base by a tedious and expensive process of refining in furnaces adapted to that purpose. The process was so costly that steel was little used except for cutlery and comparatively small articles, and was practically unknown in the construction of bridges, rails, buildings and other structures, where large quantities of iron were required.

In 1856, Bessemer discovered a process of purifying iron without the use of fuel, by blowing air through a molten mass of pig-iron placed in a refractory-lined vessel called a converter, whereby the silicon, carbon and other non-metallic constituents were consumed, and the iron thus fitted for immediate conversion into steel by recarbonization. The present process of recarbonization was a supplementary invention of Mushet, who accomplished it by the introduction of ferromanganese, or spiegeleisen, while the iron in a molten state was issuing from the converter, in which it had been purified, and was thus converted into steel. The process of running molten metal from blast-furnaces into pigs and remelting them in cupola-furnaces for use in a converter was termed the indirect process, and was generally used prior to the Jones invention.

His process is thus described by Bessemer in his patent of 1860:

The most important of these operations consist in melting the pig metal, transferring it in the molten state to the converting vessel, blowing air through it, and converting it into a suitable metal, mixing the metal so converted with a certain quantity of metal, raising the metal so converted with a certain quantity of metal, pouring the mixed metal into a fluid measuring vessel, and pouring it from thence through a suitable valve into ingots or other molds, and the removal therefrom of the ingots or other cast masses when solidified.

This invention of Bessemer, simple as it appears, may be said not only to have revolutionized the manufacture of steel, and to have introduced it into large constructions where it had never been seen before, but to have created for it uses to which ordinary iron had been but illy adapted.

While in the Bessemer specification of 1860 it is said—

the iron to be used for the purposes of my present invention may be conveyed by a gutter in a fluid state direct from the smelting-furnace where it has been obtained from the ore—

without the expense and delay incident to the intermediate cupola process, practical experience, in this country at least, showed that the refining of iron without first casting it into pigs, selecting or mixing the pigs and remelting them, was attended with such expense that the entire abandonment of the practice was seriously considered. The difficulty was in the material variations between different portions of the same cast, and even different parts of the same pig,—an irregularity which was increased when the metal was drawn from several furnaces. There was added to this frequent changes in the character and composition of the ore, coke and limestone flux with which the furnace was charged. The consequence was that the non-uniform chemical composition of the metal from the molten blast-furnaces yielded products of steel, such as rails and beams, which were not only irregular chemically, but of irregular and uncertain final condition—some sound, others of imperfect strength and full of flaws.

These irregularities were in a measure obviated, not only by a careful selection of pigs beforehand, but by the necessity of employing open receiving ladles or reservoirs into which the product of one or more cupola-furnaces was drawn off into such reservoirs, which were made large enough to hold the product of two or three furnaces, and from which the molten metal was withdrawn into the converters. Had the amount required for the converters in each case been the exact product of one or more cupolas, no reservoirs would have been necessary, but as the demand was variable, a storage of molten metal was required to retain the product of one or more cupolas, until it was required for the converters. Of course, as the product of two or more furnaces was drawn off into these receiving-ladles, there would be some intermixing of those products, although the receiving-ladles do not appear to have been used for that purpose, the operators relying more particularly upon the careful selection of pigs beforehand, to obtain the requisite uniformity for conversion into steel. The ladles being open at the top, the molten metal could not long be retained in them, and in the best practice it was so arranged that the withdrawal from the reservoir were made every few minutes, and without regard to the amount left in the reservoir after each withdrawal. It will be borne in mind that the object in either case, whether by direct or indirect process, is to obtain, as far as possible, a uniform product of iron for the converter.

These results (said one of the witnesses, (Kennedy,) speaking of the process used before that of Jones) are not obtained by the practice of taking metal from two blast-furnaces by running a train of ladles in front of them and tapping into each ladle half a charge and following it from a second furnace. By such practice, of course, there is some independent equalization of the composition of each ladle or of the ladles of each group, but it adds no further advantage, and in fact would not obviate the difficulties of direct metal working. It does not enable the converter manager to control the character of each charge from the character of the preceding charge, and would therefore ex-

hibit the uncertainty of operation and the irregularity of the product which the Jones method avoids.

It had long been an object of manufacturers that steel should be made directly from the molten metal, as it comes from the blast-furnaces, without having to pass through the intermediate or cupola process, which involved the casting of the furnace metal into pigs. These, after becoming cold, were assorted, broken up, recharged and remelted in a cupola-furnace, and then placed in a converter for conversion into steel. By this cupola process a product, practically uniform in character and suitable for further treatment in the converters, was secured, but at the expense (more than sixty cents per ton) of rehandling and remelting the iron as it came from the blast-furnaces, in cupolas, and the contamination of the metal with sulfur evolved from the coke in the process of remelting. The obstacles connected with this method and the difficulties attendant upon the use of the direct process are thus comprehensively set forth by Mr. Julian Kennedy, one of the experts:

Ever since the invention of the Bessemer process it has been well recognized that great economies could be attained by transferring the molten metal from the blast-furnace to the converter without allowing it to solidify. Until within a few years, however, this direct process, as it has been called, has not been generally used. It is easy to see why this was the case. The fluctuations in the chemical composition of the metal from the blast-furnace was too great to allow that degree of uniformity of product in the Bessemer steel produced from it, which is absolutely necessary in the case of steel rails, for example, which must be as reliable as human skill can make them, and where no reasonable expense can be spared to make them perfectly safe and trustworthy. A very few broken rails in a track, with the damage to property and human life which this might cause, would far more than offset any possible saving in a year's work, due to the use of the direct process. For this reason the practice, until within comparatively recent years, has been to cast the metal in pigs, then to analyze it and reject any portion not closely approximating a rigid specification in its chemical composition, and to select, mix and then melt the approved metal in cupola-furnaces. By this means very great uniformity of chemical composition of the remelted metal can be obtained, and good and reliable steel made from it with regularity and certainty.

Speaking of a time when the direct process (before that of Jones had been in use for several years) he said:

After studying the results which had been obtained at the Edgar Thompson works and elsewhere in the use of the direct process, I consulted with Mr. James Gayley, and we agreed that in the building of a new works it would not be profitable to use direct metal, but that on the contrary the direct metal resulting from the irregularity in the product were so great that it would be better to go to the expense of building and using cupola-furnaces. We did not then perceive any means adequate to overcome these direct metal results.

The difficulties connected with the prior devices are also stated in an article by Mr. Holley, published in 1877, from which we extract the following paragraphs:

Third. The embarrassing feature of the direct process is the irregularity in the heat—that is to say, in the silicon of the charge—resulting in the large amount of scrap due to too little of this element, and in the increased number of second quality rails due to too much of it; while in France, where three to five per cent. of manganese is the heating ingredient, there may always be an excess of this latter element without injuring the quality of the steel, although the variation of heat is here, also, a serious difficulty. In other words, it has not yet been possible to work the blast-furnace with sufficient regularity to realize approximately the theoretical advantages of the direct process.

Fourth. The obvious remedy is to mix a number of blast-furnace charges, so as to reduce the irregularity to a minimum. Two systems of doing this are on the eve of trial: the one is simply mixing a few charges in a tank that the metal will be drawn out before it chills; the other is to store a large number of charges in a heated tank—that is to say, in an immense open-hearth furnace.

A few words of history may be of interest. Mr. Bessemer's early intention was to use blast-furnace metal direct. The earlier Bessemer practice, especially that in Sweden, was with metal right from the blast-furnace. But this practice did not make headway, except where there was from three to five per cent. of manganese in the pig blown, for reasons just mentioned; so that

[Vol. 99. No. 9.]

while it soon became standard at Furness and elsewhere in France, as well as in Sweden, and to some extent in Germany, yet in England it was not only unused but pronounced impracticable so late as September, 1874.

This difficulty, and it seems to have been so serious as to render the direct process commercially impracticable, Jones sought to remedy and did remedy by creating a covered reservoir of molten metal between the blast-furnaces and the converters, in which should always be maintained a large quantity of metal, happily termed by the district judge a dominant pool, which should be drawn off in small quantities at a time, and replenished by a like quantity of metal from the blast-furnaces. In this way, while the metals taken from the several blast-furnaces might differ in their heat and constituent elements, yet being received and mixed with the molten metal in the dominant pool, they were, when discharged from the reservoir, approximately, though not perfectly, uniform, the original variations having been lost in their mixture with the dominant pool.

It is therefore plain [says the district judge in his opinion] that with a mixer thus organized, it is possible to have wide variations in the composition of the blast-furnace metal charges added, and at the same time the successive withdrawals from the Bessemer converter show quite small and gradual changes of composition. The heat of the dominant mass is affected by the incoming charges just from the blast-furnaces, but the heat of such addition, whether relatively high or low, must mingle with, be modified by, and average with, the heat of the larger and dominating mass.

It is not insisted that this method gave absolutely uniform results—

nor [says the witness Fry] did the inventor, as I understood him, comprehend such, but, on the contrary, he recognized the practical impossibility of rendering uniform a continuous supply of metal, and desired only to reduce the abrupt changes of the several portions added to the gradual changes of the portions withdrawn, and this is what he worked out from his invention in a thoroughly practical way.

While the patent in suit is for a process and not for a mechanism, the process will be the more easily understood by a reference to the apparatus above reproduced, which consists of a reservoir, or closed receptacle, commonly termed a "mixer" lined with fire-brick of sufficient thickness to retain the heat of the molten iron, and of such size and strength as to be capable of receiving and retaining a large amount—"say one hundred tons"—of molten iron. This reservoir is mounted upon journals, and is adapted to be tipped so as to receive at one end molten metal from the blast-furnaces, carried to it in cars, and by being tipped in the other direction, to discharge the same into similar cars, in which it is carried to the converter. The essence of the invention lies in the fact that the tip is so regulated by a stop that the reservoir can never be wholly emptied, but a "considerable quantity" of metal always remains—a dominant pool, into which successive additions are received.

That the invention is one of very considerable importance is attested by the fact that it was not only put into immediate use in the Edgar Thompson works at Braddock, then owned by the plaintiff, but has since been adopted by all the leading steel manufacturers in this country, and by many similar works in Europe, where the patent was sold for ten thousand pounds. Mr. Carnegie, one of the witnesses, says of it:

There were both advantages and disadvantages [in the direct process used prior to Jones's invention], but the disadvantages

were so great, that we often debated whether to abandon the process or not. We found it impossible to get a uniform quality of rails, as well as by the cupola method. . . . When we were still anxiously struggling with the problem, and undecided whether to continue or abandon it, Captain Jones . . . told us that he believed he had invented a plan which would solve the problem. . . . We thought so well of the idea—I was as convinced of its reasonableness—that I directed him to go ahead with his invention. . . . Captain Jones did so, and almost from that day our troubles ended. He had scored a tremendous success; another step forward was taken in the manufacture of steel, and we are using the invention to-day. . . . Without this invention I believe that we should have abandoned the mode of running direct from the blast-furnaces. Above all things, the manufacturer has to regard the uniformity of product, the quality of rails, and this uniformity cannot be obtained without Jones's invention, as far as I know.

It is true that what is termed the direct process was used in connection with the Bessemer invention in some foreign countries, notably Sweden and France, with more or less success; due to the peculiar character of the ores used in those countries; but such attempts in this country had proven practically failures, and had been abandoned. In regard to this the witness Kennedy said:

The Jones method has made the direct process, which was attended with great danger and difficulties before the date of his invention, a thoroughly practicable and successful one. Instead of it being a question of great doubt whether to run the metal direct to the converter or vessel it, as it was up to the time of Jones's invention, we now would now think of building a new works, containing both blast-furnaces and converters, without arranging to mix the metal by the Jones method, which not only effects an immense saving in the cost of operating the works, but makes a uniformly good product to be made, and also a purer product than can be obtained from cupola metal, which is abundant and is contaminated by sulfur from the coals which constitutes the fuel of the cupola.

Indeed, the value of the process is not wholly denied, though much depreciated, by the defendant, which relies rather upon the fact that it was well known in the art, and that so far as it is described in the Jones specification and drawings it was not infringed by it.

1. We now proceed to an examination of the question of *anticipation*, in support of which a number of English patents are produced, which will be briefly considered: First, the British patent to Taberner of 1856, the object of which was, as stated by the patentee in his specification—

to dispense with the necessity of employing one or more large furnaces, and to use in lieu thereof several small furnaces, the combined capacities whereof are equal to that of one or more large furnaces, and to cause these small furnaces to discharge their contents at short intervals of time into one large reservoir, from which the molten metal may be drawn for casting from.

The principal features in this invention consist in directing the blast to the body or belly of the furnace, as well as to the hearth thereof, for the purpose of fusing or melting the entire mass of ore in the furnace simultaneously, or nearly so. . . . The mode hitherto practiced in smelting-furnaces has been to direct blasts into the hearth only thereof, thereby requiring several hours to smelt or fuse the contents of a large furnace.

The specification is somewhat blind, and it is difficult to see what definite or valuable result is obtained by the use of several small instead of one large furnace, except perhaps a quicker heating and less delay in its practical operations; but it is sufficient for the purposes of this case to say of it that it contains no suggestion of a mixing of different casts for the purpose of obtaining a more uniform product, and that the invention has no relation to a further treatment or refining. It does contemplate the use of a reservoir, but there is no suggestion of a reservation in such reservoir or a quantity of molten metal. It is not denied that the use of a reservoir from which molten metal may be drawn long antedated the Jones patent. But the best that can be said of the Taberner patent is

[Vol. 95, No. 8.]

that, if the reservoir had been of sufficient size and properly constructed so as to never be completely emptied, it might have been adapted to carry out the Jones process; but there is no evidence that it was ever so constructed, or that the production of a uniform discharge from the reservoir was contemplated. That it could not have been intended for the purpose of carrying out the Bessemer process, or any other process, for the use of blast-furnace metal in a converter, is evident from the fact that the patent was nearly simultaneous with the Bessemer patent, of the existence of which the patentee appears to have been entirely ignorant.

The English patent to Deighton of 1873, for "improvements in the arrangement and mode of working an apparatus for the manufacture of Bessemer steel," contains the closest approximation to the principle of the Jones invention. If this does not anticipate, none does. The primary object of the patent seems to have been to prevent the loss of time while the converters are being cooled and relined or repaired, and again prepared for work, by providing that the converting vessel shall be so arranged that it can be readily detached from its actuating mechanism and lifted bodily out of its bearings by a suitable crane, or other lifting mechanism, and a spare converter substituted in its place.

There is, however, a further provision in the patent, as follows:

Instead of manufacturing Bessemer iron or steel from pig-iron, which has to be melted in cupolas, my invention also consists in taking the molten metal directly from the blast-furnace to the converter, in which case I prefer to arrange the Bessemer plant in a line at a right angle to a row of two or more blast-furnaces, and place a vessel to receive the molten metal tapped from two or more blast-furnaces to get a better average of metal which will be more suitable for making Bessemer steel or metal of uniform quality, the vessel or receiver being placed on a weighing-machine so that any required weight may be drawn or tapped from it and charged into the converter.

The specifications provide for manufacturing Bessemer steel directly from the smelting-furnace by employing gates or channels for molten metal from each furnace, leading to a reservoir, which is placed low enough to give fall for the molten metal to flow from the blast-furnace to this reservoir, which forms a receptacle for mixing the molten metal from two or more of the smelting-furnaces. From the reservoir, the mixed molten metal is tapped and flows down the swivel-trough into the converter. By placing the reservoir on a weighing-machine, it can be readily ascertained when the exact quantity required has been tapped from it into the converter.

The sixth claim of the patent is for—
the system or mode of arranging and working Bessemer converters with a receiver or receptacle for mixing the molten metal from two or more smelting-furnaces to get a more uniform quality of metal, substantially as hereinafter described and illustrated by the drawings.

While Deighton seems to have conceived the idea that uniformity of product was necessary to the successful use of the direct process, and might be attained by mixing the discharge from several blast-furnaces in an open reservoir, standing between the furnaces and the converter, the dominant idea of the Jones invention, that a constant quantity of molten iron should always be kept in each reservoir to serve as a basis for such mixture and an equalizer of the different discharges, does

[Vol. 95,

not seem to have occurred to him. As the discharge-pipe was located at the bottom of the reservoir, it was certainly possible to empty it entirely, and the testimony in the case indicates that this was the natural method of operation. If this were so, then the reservoir accomplished nothing beyond the mixing of each batch of metal introduced into it from the different blast-furnaces. There is nowhere in the specification a suggestion of supplying to and withdrawing from the reservoir small amounts at a time, a constant quantity of metal being retained in the reservoir for the purpose of equalizing the different products of the blast-furnaces. While the Deighton reservoir, if a cover had been added to it, might perhaps have been utilized for that purpose, there is no evidence that such use ever occurred to the inventor. Indeed, the absence of a cover to the reservoir is evidence, even to a non-expert, that it was not contemplated that a permanent quantity of molten iron should be retained in it, since a radiation of heat would thereby be produced and the contents skulled or crusted over with a layer of refuse iron or slag. The testimony is clear that the Jones process cannot be carried on in an open reservoir, and the absence of a cover is conclusive that it is not so used.

It is insisted, however, that defendants have demonstrated, by practical experimentation with a plant constructed according to the specification of the Deighton patent, that the results are practically the same as those obtained by the Jones process. This plant, however, was constructed after suit brought, long after the Deighton patent had been allowed to expire, and with no opportunity afforded the plaintiffs to inspect the plant or witness its operation. The tank was fitted with a cover, and a constant pool of molten metal retained in it; but this was not the Deighton process, but the Jones process adapted to the Deighton device. Were this evidence admissible at all, we are satisfied that it is met by the fact that if the Deighton patent had been adaptable to the Jones process, it is scarcely possible that its merits should have failed to seize upon the attention of manufacturers, who would have brought the patent into general use, instead of allowing it to lapse for the non-payment of a comparatively small fee. As something in the nature of the Jones process was needed to enable steel to be manufactured directly from the product of blast-furnaces, the utility of the Deighton patent for that purpose would at once have been recognized and its success assured. But evidently that patent was not the final step in the accomplishment of the mixing process. It contributed nothing to the art of manufacturing steel, and, although issued in 1873, was allowed to lapse in 1876, after an apparently unprofitable existence for three years, by reason of the non-payment of the stamp duty necessary to keep it alive. It is sufficient to say of it that it fails to disclose, fully and precisely, the essential features of the process covered by the Jones patent. (*Walker on Patents*, sec. 54; *Seymour v. Osborne*, 11 Wall., 516, 555; *The Caywood Patent*, 97 U. S., 704.)

No. 8.]

Although Deighton was an employee of the Moss Bay Company of Workington, England, if any attempt were made by this company to make use of his process, it evidently amounted to nothing, since one of the writers, Snelius, contributing to the *Journal of the Iron and Steel Institute*, 1878, says:

One great drawback to the direct-casting process was that you could not always get your metal at the exact time you wanted it. He believed that it would be found that the great advantage to the Bessemer works in America had been the intermediate receiving-ladle, which was designed by Mr. Holley, and which was universally used there, although it was never used in England. The Moss Bay Company attempted to modify the thing some time ago, and put up a heating-furnace; but that, to his mind, was a step in the wrong direction. Anyhow, the thing had failed, and no one in England, so far as he knew, was using any intermediate receiver between the blast-furnace and the converter.

This defense presents the common instance of a patent which attracted no attention, and was commercially a failure, being set up as an anticipation of a subsequent patent, which has proved a success, because there appears to be in the mechanism described a possibility of its having been, with some alterations, adaptable to the process thereafter discovered. As hereinafter observed, a process patent can only be anticipated by a similar process. It is not sufficient to show a piece of mechanism by which the process might have been performed.

In the American patents to Durfee, Nos. 118,997 and 122,312, both of 1871, the desirableness of manufacturing steel directly from the blast-furnace is recognized, and in his second patent he says:

That in the manufacture of steel by the pneumatic or Bessemer process, a great saving of fuel and iron, of wear and tear of furnaces, and of labor would be effected were it possible to make uniformly good products of the desired temper by converting the crude iron immediately as it is tapped from the blast-furnace in which it is made. This plan has been and may still be practiced to a considerable extent, but it has been found that by reason of the irregular working of blast-furnaces, and the consequent varying character and quality of the crude iron produced, it was always very difficult and in most cases impossible to secure such uniformity in the converted metal as was essential to success in the business. Hence, at several establishments where the plan of taking the fluid iron as it was tapped from the blast-furnaces and pouring it at once into the converter has been practiced, it has been abandoned, the proprietors preferring to incur the expense of handling and remelting the crude iron after it had been cast into pigs in order thus to secure the advantage of carefully selecting and mixing the materials for each charge to be converted.

He proposed to accomplish this by using a reverberatory gas-furnace, into which the crude iron from the blast-furnace is poured, and in which it may be mixed with other irons, and so treated as to insure uniformity. Pig-iron of different qualities, or any metals or metalloids or fluxes can be added and mixed with the metal as may be necessary to bring it to the required character. The process is so manifestly different from that described by Jones that it demands no further attention. If it were put in practice at all, it seems to have proved a failure, as, although an English patent was taken out by Durfee, it was allowed to lapse by reason of the non-payment of the stamp duty.

Two American patents to James P. Witherow, No. 315,587 and No. 327,425, both issued in 1885, are pressed upon our attention. In the second patent, the only one necessary to notice, he restates the advantages of the direct process and the difficulties theretofore encountered in its practical operation.

In the manufacture of steel by the pneumatic process, the converters are charged with molten metal, the product of the blast-furnace. This metal is usually cast in the form of pigs, then remelted in the cupola as needed before being charged into the converter. . . . It is very desirable to take advantage

of the molten condition of the metal as it comes from the blast-furnace for its use in the converter, because thereby the remelting of the metal and the expense of the conversion of a pig into molten metal may be avoided. The charge of the converter is from one to five tons, and the casting of a blast-furnace runs usually from ten to fifty tons. The difficulty of using the molten metal from the furnace in the converter consists in keeping the large quantity of metal from the latter in a proper molten condition for use in the former.

He proposed to remedy this by a reservoir provided with a suitable cover and with twyers—which blow down upon the surface of the metal for the purpose of maintaining its heat and fluidity.

As this reservoir was apparently adapted to hold only a single cast, and therefore must be emptied before another cast was received into it, it was impossible that Witherow intended by its use to practice the Jones process. There is no suggestion anywhere in the patent of a desire to retain a quantity of metal in the reservoir to serve as a basis for mixing the various products of the blast-furnace, which was the dominant idea of the Jones patent. To anticipate a process patent, it is necessary not only to show that the prior patent might have been used to carry out the process, but that such use was contemplated, or that the leading idea of the Jones patent of maintaining a dominant pool in the reservoir was such a use of the Witherow patents as would have occurred to an ordinary mechanic in operating his device. Whether the reservoir in the Witherow patent was partly or fully emptied, seems to have been a matter of complete indifference to the inventor, and the idea of maintaining a constant quantity therein seems to have never been conceived by him. His design seems to have been merely to provide a reservoir for the storage of the large quantity of metal from the blast-furnace, and to maintain its heat until the comparatively small quantities required in the converters had been drawn off for use. As he states in his specification:

The metal is usually tapped from a blast-furnace once in every six hours, and the quantity thus cast is many times in excess of the charge of a converter, [which] is from one to five tons. [While] the cast of a blast-furnace runs usually from ten to fifty tons. [While] the metal is tapped from the blast-furnace once in every six hours, the time between charges in the converter is usually twenty minutes and upward, and the metal in the furnace must be kept in condition to be tapped from time to time into the converter as needed.

This appears to have been the whole object of the invention.

The same remark may be made of all these prior devices. While all contemplate the reservoir between the blast-furnaces and the converters, such reservoir is used for storage and for such incidental steps toward uniformity as the necessary mixing of the different products of the blast-furnace would lead to, while in none of them is there a provision for supplying and withdrawing from the mixer such quantities of metal at a time and the retention of a considerable quantity of metal in the reservoir as a necessary prerequisite to that uniformity of product which was recognized as the great desideratum and was the constant effort of manufacturers to secure. Granting that some of these devices may have been made use of to carry out the Jones process, none of them in practical operation seems to have been effective to secure the desired result. A process patent, such as that of Jones, is not anticipated by mechanism which

[Vol. 22, No. 8.]

might with slight alterations have been adapted to carry out that process, unless, at least, such use of it would have occurred to one whose duty it was to make practical use of the mechanism described. In other words, a process patent can only be anticipated by a similar process. A mechanical patent is anticipated by a prior device of like construction and capable of performing the same function; but it is otherwise with a process patent. The mere possession of an instrument or piece of mechanism contains no suggestion whatever of all the possible processes to which it may be adapted. (*New Process Fermentation Co. v. Maus*, 39 O. G., 1419; 122 U. S., 418, 426.) If the mere fact that a prior device might be made effective for the carrying on of a particular process were sufficient to anticipate such process, the absurd result would follow that, if the process consisted merely of manipulation, it would be anticipated by the mere possession of a pair of hands.

True, if the process were the mere function of a machine, another machine capable of performing the same function might be an anticipation; but this is not because a process can be anticipated by a mechanism, but because, as we have held in several cases, the mere function of a machine is not patentable as a process at all. (*Cornings v. Burden*, 15 How., 352; *Ridson Locomotive Works v. Medart*, 71 O. G., 751; 138 U. S., 68.)

To enable the Jones process to be successfully carried out it is necessary (1) that the intermediate reservoir or mixer should be of large size, "say one hundred tons" capacity; (2) that it be covered to prevent the access of cold air from without; (3) that it be provided with a stop, so that it may not be tilted so far as to be emptied of its contents; (4) that a quantity of molten metal so large as to absorb all the variations of the product of the blast-furnace received into it and thus to unify the metals discharged into the converters, be constantly retained in it. None of the prior patents or processes to which we are referred meets these requirements. Indeed, it is scarcely too much to say that none meets more than one of them. When we add to this that none of them was ever used, or was ever susceptible of being used, without material alteration, to carry out the Jones process, it is evident that the defense of anticipation by prior patents rests upon a slender foundation.

Certain discussions, reported in the *Journal of the British Iron and Steel Institute*, are relied upon as embodying a description of the Jones process. Running through all these discussions, there is the same idea of the difficulties experienced in the practical carrying out of the direct process by reason of the want of uniformity in the different products of the blast-furnaces, and the possibility of remedying this and thereby doing away with the expense of remelting the pig-iron in cupolas by a mixture of such products in a reservoir intermediate the furnaces and the converters; but the dominant idea of the Jones patent, of maintaining a permanent and large quantity of molten metal in the mixer for that purpose, does

2000-2-111

not seem to have occurred to any of the writers upon the subject. Through all these papers, there is an admission of practical failure in the efforts theretofore made to obviate the difficulty, and a half-expressed hope that American ingenuity might ultimately solve the problem. Some of the expressions, taken by themselves, seem to foreshadow the Jones idea; but there was nothing in any of these discussions that filled the requirement of the law, (R. S., sec. 4896,) of a description in a publication sufficient to anticipate the patent.

In some of the very works where attempts had been made to adopt a direct process, they were abandoned as unprofitable, and the Jones invention subsequently adopted. The witness, David Evans, manager of certain iron-works in England and Wales, sums up his testimony in the following answer:

Prior to the invention of Captain Jones several firms used the direct process, but the results were not very satisfactory, as explained before, through want of uniformity. The results obtained gave a large number of defectives. But since the adoption of the mixer at the various works where I have been engaged, we have reduced the defective or second-class rails fully one-half, and also saved the remelting.

Indeed, it is stated by several of these writers that the adoption of the Jones invention reduced the defective rails to something like half of what they were before.

Our attention is also challenged to certain unpatented practices, among which is one known as the Whitney foundry practice for the casting of car-wheels, wherein the metal is tapped from three cupolas into an open reservoir of eight to ten tons capacity, permitted to mix and even up in it, and the charges withdrawn to be cast into car-wheels, the reservoir being maintained half-full. The practice was to run the metal from the cupola-furnaces into the reservoir-ladle until it was nearly full, then to begin pouring out charges into the casting-ladles, while still continuing to pour metal into the ladle from the furnaces, the ladle being kept approximately full during the working day, when it was emptied and refilled on the following day. Aside from the fact that this process has only to do with cupola metal, uniformity in which was largely secured by a careful selection of the pig-iron charged into the cupola-furnaces, and had no reference whatever to the direct process of charging converters with the product of blast-furnaces, it appears that, while Whitney recognized the fact that the charges of iron from the cupolas when run together into the ladle would mix, it appears that with this running together of the different charges, the mixing operation ended. The maintenance of a permanent pool, and the constant pouring in and out in ladles—the essence of the Jones invention—had nothing to do with the process. Indeed, it may be doubted whether the mixing of the cupola metal was of any substantial value. Evidently it suggested to no one the Jones process. It is now too late to insist that it would have been suggested to any mechanic of ordinary skill and intelligence. But if the Whitney practice were primarily for the purpose of mixing, and were adequate for that purpose when

court did not seem to look upon it as the turning point of the case, nor do we regard it as at all decisive. It seems to assume that the second claim can only be met by evidence of absolute uniformity of product, whereas all that is claimed is a uniformity in the constituent parts of molten metal preparatory to further treatment. In other words, to make it fit for further treatment in the converters, without the necessity of remelting in the cupola-furnaces. Or, as stated by the district judge:

It is therefore plain that with a mixer thus operated, it is possible to have wide variations in the composition of the blast-furnace metal charges added, and at the same time the successive withdrawal for the Bessemer converter show quite small and gradual changes of composition. The heat of the detained mass is affected by the incoming charges from the blast-furnace, but the heat of such addition, whether relatively high or low, must mingle with, be modified by and average with the larger and dominant mass.

With regard to this portion of the opinion, counsel for defendant observes:

The judge of circuit court, having lost sight of the statutory requirements as to a full, clear and concise statement of the invention, and having persuaded himself that it was his judicial duty to find a way if possible to protect the Carnegie Company in its monopoly of what Mr. Gayley and his colleagues claim ought to have been the invention described in the patent, adopted the ingenious view that the patent was to be construed as though it disclosed and covered two inventions, one having for its object to obtain a product substantially uniform in its contained silicon and sulfur, and the other having for its object the improvement in the operation of bessemerizing iron which is incident to an avoidance in the successive charges of abrupt variations in contained silicon.

We have not, however, been able to persuade ourselves that the two processes are so alternative and inconsistent with each other as to render them mutually destructive, or to justify counsel in charging the district judge with an abdication of his judicial duty of deciding the case according to what he believed to be the law and the facts. We dismiss the subject with the simple observation that much more seems to have been made of it than it deserves, and that a reference to the second claim shows its object was to secure uniformity of the molten metal in its constituent parts preparatory to its further treatment, by which further treatment we are to understand the bessemerizing process of converting metal into steel, and that any step in that direction would necessarily lead to an avoidance of abrupt variations in silicon and sulfur, while such avoidance of abrupt variations would in their turn only tend toward a greater uniformity of product.

Some criticism was made upon the action of the court in permitting a disclaimer of certain clauses in the specification, printed above in *Italics*, which was made after the argument and upon the petition of the plaintiff—

that at the hearing of this cause it was taken by surprise by the argument of the defendant that the portions of the specification now disclaimed enlarged the scope of the invention of the said Letters Patent beyond what your petitioner believes to be the import of the claims thereof.

Upon the hearing defendant seems to have insisted that certain portions of the specifications were broader than the second claim. Those parts of the specification therefore were disclaimed. As we had occasion to observe in *Sessions v. Romadka*, (59 O. G., 989; 145 U. S., 29)—

the power to disclaim is a beneficial one, and ought not to be denied except where it is resorted to for a fraudulent and deceptive purpose.

In that case the plaintiff was permitted to enter a disclaimer of all the claims but the one in suit, [Vol. 92,

the patentee having included in the patent more devices than properly could be the subject of a single patent. In the case under consideration the disclaimer was not of a claim but of certain statements in the specification, which if retained might be construed to have the effect of illegally broadening the second claim. The first statement disclaimed was that the invention might be practiced by merely receiving a number of small portions of metal taken from different ladles, the mixing being performed merely by the act of pouring into the charging-ladle. The use of the word "merely" ignored the steps embodied in the second claim, where the mixing is not performed by merely pouring together the several charges into a ladle, but by maintaining a permanent quantity of metal in the reservoir, to which charges were alternately added and from which they were withdrawn. The other clauses were intended to disclaim the casting of the metal into pigs. We think there is no force in the criticism that a disclaimer may not extend to a part of the specification, as well as to a distinct claim. (*Husbut v. Schilling*, 47 O. G., 1067; 180 U. S., 456; *Schilling v. Gunther*, 17 Blatch., 66; *Schwarzwalder v. New York Filter Company*, 26 U. S. App., 547.) Had the purpose of the disclaimer been to reform or alter the description of the invention, or convert the claim from one thing into something else, it might have been objectionable, as patents can only be amended for mistakes of this kind by a reissue. But the disclaimer in this case appears to have been made to obviate an ambiguity in the specification, and with no idea of obtaining the benefit of a reissue. If the clauses had the effect of broadening the patent the disclaimer removes the objection. If they did not, the disclaimer could do no harm, and cannot be made the subject of criticism.

It is insisted, too, that there is no mention in the second claim of a dominant pool, and that the words—

removing portions only of the composite molten contents of the receptacle without entirely draining or emptying the same, and successively replenishing the receptacle with fresh uniform additions—

are satisfied by leaving a quantity of iron, however small, in the reservoir, and that it really includes nothing that was not well known before. It is true that neither the size of the reservoir nor the amount of metal to be left therein, after each discharge is made into the converter, is specified, but it is stated in the specification that this reservoir may be of any convenient size—

holding, say, one hundred tons of metal (more or less)—

with the bottom of the discharge-spout some distance above the bottom of the vessel—

say, two feet in a hundred-ton tank, and more or less according to the capacity of the vessel, the purpose of which is that when the metal is poured out of the spout a considerable quantity may always be left remaining and unpoured, and that whenever the vessel is replenished there may already be contained in it a body of molten metal with which the fresh additions may mix.

Though the size of the reservoir and the considerable quantity left therein as a dominant pool might have been described more definitely, (but perhaps at the risk of an infringement being avoided by one using a receiver of a different size

[Vol. 92,

containing a different quantity,) we think it is impossible to read this patent without gathering from it the dominant idea of Jones not to describe a reservoir for storage, with or without incidental mixing, but to provide a receptacle the main, if not the sole, object of which is to preserve therein a large and constant quantity of molten iron as a basis for a gradual unification of the product of several blast-furnaces, or of several casts from the same furnace, and herein distinguishing it from all prior inventions. The specification of the patent is not addressed to lawyers, or even to the public generally, but to the manufacturers of steel, and any description which is sufficient to apprise them in the language of the art of the definite feature of the invention, and to serve as a warning to others of what the patent claims as a monopoly, is sufficiently definite to sustain the patent. He may assume that what was already known in the art of manufacturing steel was known to them, and, as observed by Mr. Justice Bradley, in *Webster Loom Co. v. Higgins*, (31 O. G., 2031; 105 U. S., 580, 586:)

He may begin at the point where his invention begins, and describe what he has made, that is new, and what it replaces of the old. That which is common and well known is as if it were written out in the patent and delineated in the drawings.

We think this second claim not only describes with sufficient clearness the purpose of the patent to secure uniformity of the molten metal in its constituent parts preparatory to further treatment, but read with the specification sufficiently describes the process by which this uniformity may

be secured, by always preserving in the reservoir a sufficient quantity of molten metal to secure such uniformity of product. It is undoubtedly true that the storage feature appeared more prominently in the specification which was first rejected upon the ground that it was not sufficiently differentiated from prior patents, than in that which was finally accepted, but there is nothing to indicate that Jones did not understand from the first that the distinguishing feature of his invention was the preservation of a considerable quantity of iron in the reservoir.

3. The question of *infringement* only remains to be considered, and, in the view we have taken of the prior devices, presents no serious difficulty. The court of appeals was of opinion that—

the defendant's reservoir, or accumulating-ladle complained of, is the same in principle as one which has been in use at the Cambria works ever since Bessemer steel was first manufactured there, with only this difference, that at first it was used at cupola, now at furnace.

If such were the fact, of course defendant would not be open to the charge of infringement. Undoubtedly it has the right to make use of all prior devices, and particularly such as had been used at its own manufactory. In order to understand the device made use of by the defendant prior to the Jones invention, we reproduce herewith two small but easily understood cuts, taken from its brief, showing the character of the ladle known as the Bessemer intermediate ladle, used by it and generally by all American mills manufacturing steel by the Bessemer process.

It appears elsewhere in the testimony that the intermediate reservoir or ladle was from fifteen to eighteen tons capacity, and the converter from six to eight tons; that the molten metal was tapped from the cupolas into the reservoir and withdrawn for the converter, and as the intermediate ladle held considerably more than the amount of metal necessary to charge a converter, there was some incidental mixing; but the main and perhaps the only purpose of the reservoir was for storage, and that if any quantity of metal were left in the reservoir it was by accident rather than by design. It will be noticed, too, that the reservoir was open at the top. It does not appear to have been made use of in carrying out what is known as the direct process, the difference being that the cupola

[Vol. 92,

practice furnished a metal for the Bessemer converter that was uniform in composition, or practically so, while the direct metal was largely variable in composition.

The testimony further shows that, after the installation of the Jones mixer at the Edgar Thompson works, Mr. Morgan, the defendant's mechanical engineer, visited and inspected these works and obtained information as to their practical operation, and was advised by the superintendent as to the location and proper size of the mixer and its contiguity to the converters. Mr. Morgan does not deny this conversation, although he qualifies it by saying that he thought the Jones apparatus had grave defects. Shortly after this visit, and in the latter part of 1895, defendant installed an ap-

[Vol. 92,

paratus of its own for the operation of the direct process, which is herewith produced upon a small

1870h LADLE
BLAST FURNACE
TAP 10 TO 150
TONS.

tie-shaped vessel of about three hundred tons capacity, arranged to tilt, and having a spout at either side for receiving and pouring out the metal. The metal was brought to the mixer and poured in at one end, and through a spout on the other side, was poured into a ladle, which supplied the Bessemer converters. The metal was supplied both from blast-furnaces and cupolas, the former furnishing about two-thirds, the latter about one-third of the metal used; but the metal from the cupola system was delivered by a ladle to the converter direct, and not through the reservoir. The metal from the blast-furnace entered the reservoir in about fifteen-ton ladle lots, and was withdrawn in approximately twelve-ton lots. The chief engineer of the company states that—
in accordance with the natural way of using the reservoir, it is ordinarily kept well filled up.

That in the practical operation of the mixer or reservoir a large quantity of iron was retained for mixing purposes is evident from the fact that a chalk-mark was made on the side of the mixer, which was not allowed to run below the floor, as a guide to the men who rotated or tilted the mixer, since, if the mark went below the floor and out of sight, they could not tell how much iron was left in the mixer. Under these instructions not to allow the chalk-mark to go below the floor there was retained in the mixer about one hundred and seventy-five tons of molten metal, amply sufficient for the purposes stated in the Jones patent. Its principle of construction was similar to that of the Jones mixer, and its operation identical. Indeed, defendant's engineer himself says:

With the exception of additions of cupola metal I do not know that there is any material difference between our practice and that described in the second claim—

of the Jones patent. We agree, in the opinion of the circuit court, that—

It is quite clear, in view of these facts, that infringement takes place. That initial mixing rather than storage is the purpose of the reservoir is shown by the fact that the cupola metal is not stored, but served direct in ladles to the converter plant. And that the homogeneous mixture, once obtained, is used as a dominant pool to produce a graduated, non-errupt product, is shown by the chalk-line minimum limit of one hundred and seventy-five tons. With such a permanent dominant pool in constant use, we are clear that respondent's practice infringed the second claim of the Jones patent in both letter and spirit.

If the contents of the mixer used by defendant were allowed habitually to become empty in carrying out its process, there would be no infringement; but all the evidence contradicts this. In

[Vol. 99,

scale, and in comparison with the Jones process. It consisted of a covered refractory lined and tur-

20 TON LADLE
BLAST FURNACE TAP
20 TO 40 TONS.

the Jones practice this cannot be done, since the mixer cannot be tilted beyond a certain point. In the defendant's mixer it can be done, but is not, since the operator is not allowed to tilt it beyond a certain point gaged by a chalk-mark. This seems to be the only foundation for the charge so frequently reiterated, and in varying language, that the methods in use before the Jones process deprived that process of all novelty, and if novelty existed it was by reason of the varying modes of executing such methods; the inference from this being that as the Jones method was old, it could only be treated as new because of the conduct of individuals in applying the method and their intentions, and that this reduces itself to the proposition that the Jones patent rests upon the mere intention or minds of persons. If we understand this argument correctly, it is that the prior method contemplated storing only, and the mixing was but an incident, while the Jones patent contemplates mixing as its main object and storage only as an incident.

This proposition that the application of this patent depends upon the individual intent of the operator overlooks the essential nature of a process patent. The directions and specifications of such a patent are addressed to those engaged and skilled in the art. It professes to disclose a method of procedure, not the particular instrumentality that may be employed. It may be, as suggested, that one person may, and in ignorance of the patented method, make use of a reservoir merely as such, and without any desire to avail himself of the patented process; but such a fact would not deprive the discoverer of the process of the protection of his patent. Such a supposed case might present a question of fact for a court or jury, and if it were made to appear that the party charged with infringement had, as in this case, changed the instrumentalities used by him after a new method had been disclosed, and particularly if he had for the first time used a special device necessary to that process, a jury might well refuse to believe and find that the defendant was only following the old methods of procedure, and not seeking to avail himself of the plaintiff's invention.

But we think the difference in the two processes may be illustrated by a very simple example: Let

No. 8.]

us imagine a reservoir containing, say, three quarts, and filled with one quart each, of three liquids of different constituent parts, and withdrawn for further treatment at the rate of one or two quarts at a time. Necessarily there would be some incidental mixing, but it would occur at once that the main object of the reservoir was a retention of a sufficient quantity of the mixture to supply the receptacle for further treatment, and if no necessity existed for a longer retention of the liquid in the reservoir, it could be very quickly emptied by two discharges into the receiving vessel. Now, let us substitute for this reservoir a cask of, say, sixty quarts, into which the liquids of different constituent parts are poured in at one end from a multitude of receptacles, and discharged at the other end after remaining a certain time in the cask, and that this cask could not be tilted so far but what a quantity of liquid would be left within it amounting, say, to half its capacity. Now, if there be no distinction between these two operations there would be little left to the Jones process, the very vitality of which consists in the size of the cask relative to the ladles and the mixing of the various liquids poured into it before they are withdrawn.

If, as insisted by the defendant and found by the court of appeals, the reservoir now used is the same in principle as the one which had been in use at the Cambria Iron Works ever since the Bessemer steel was first manufactured there, and the same were adequate for the purposes of the direct process, why was any change made? Therein we think the court of appeals made its most serious error. The defendant had an unquestioned right to manufacture steel, as it had been accustomed to do; but instead of that it abandons the Bessemer uncovered ladle of twelve to eighteen tons, and adopts a covered refractory-lined reservoir of three hundred tons capacity, and makes use of it, not as before, for the storage of cupola metal, but for the mixing of blast-furnace metal according to the direct process. This, too, was done immediately after Mr. Morgan's visit to plaintiff's works.

It is true that with the growth of the production of furnaces from fifty tons a day in 1873 to four or five hundred tons in 1885 all apparatus would naturally be increased in size; but why was the open reservoir theretofore used for cupola metal provided with a cover and enlarged in its capacity from fifteen to three hundred tons—twenty-fold, while the converter was little more than doubled in size? Why was it so operated that one hundred and seventy-five tons were left in the mixer as a dominant pool; if no infringement were contemplated? In the face of these facts the question so earnestly pressed by the defendant, whether the "method of mixing molten metal," covered by the second claim, was one for securing a substantial homogeneous composition of metal, to the end of getting a practically uniform product, or was one simply for the purpose of preventing sudden variations in the compositions of successive small portions drawn from the reservoir, without attaining substantial uniformity, loses most of its signifi-

[Vol. 99,

cance. We do not know how the process can be better described than in the specification itself:

To provide means for rendering the product of steel-works uniform in chemical composition.

The variations in such composition are said to be "particularly in silicon and sulfur," and the process to be one of mixing, whereby the particles of metal—

are diffused or commingled thoroughly among each other, and the entire charge is practically homogeneous in composition, representing in each part an average of a variety of uniform constituent parts, all the charges of the converter from time to time will be substantially uniform.

This, denuded of all hypercriticism, is the object of the Jones invention, which seems to be the only one yet devised for carrying on what is known as the direct process. If it be true that this process cannot be carried on without infringing the Jones patent, he is certainly entitled to a monopoly of the invention. If it can be, then every method theretofore known for carrying on such process was open to the defendant. But we think the change from the Bessemer intermediate ladle to the Jones mixer was a radical one, and was made for a purpose. That purpose was clearly the adoption of the Jones process.

It is true that before the facts were fully ascertained, a stipulation was signed to the effect that the—

amount of molten metal in said mixer (defendant's) varies from nothing to its full capacity, depending on the supply and demand, the supply being generally sufficient to keep the mixer more than half full of molten metal, which metal remains molten therein.

It appears, however, that upon the facts being more fully ascertained, notice was given that in so far as the stipulation varied from the facts appearing in the testimony of defendant's expert, it would be repudiated, and particularly that portion wherein it was said—

that the amount of the molten metal in the mixer varies from nothing to its full capacity.

As it clearly appears from the mouths of defendant's own witnesses (notably Mr. Morgan) that, in the usual operation of the mixer, the ordinary amount of metal kept in the reservoir was more than one-half its capacity, we think that plaintiff's case should not be prejudiced by this stipulation. Stipulations are ordinarily entered into for the purpose of saving time, trouble or expense, and in this case it recites that—

as defendant's counsel is expected to sail for Europe in a few days and may not be back for about four months, it is therefore stipulated by counsel for both parties, to save delay, as follows.

But while the stipulation is undoubtedly admissible in evidence it ought not to be used as a pit-fall, and where the facts subsequently developed show, with respect to a particular matter, that it was inadvertently signed, we think that upon giving notice in sufficient time to prevent prejudice to the opposite party, counsel may repudiate any fact inadvertently incorporated therein. This practice has been frequently upheld in this and other courts. (*The Hiram*, 1 Wheat., 440; *Hurt v. Hollingsworth*, 100 U. S., 100, 104; *Malin v. Kinney*, 1 Caines, 117; *Barry v. Mut. Life Ins. Co.*, 53 N. Y., 586.)

In short, we are clearly of opinion that the reservoir now in use is used for entirely different pur-

Es U.]

process from the intermediate Bessemer ladle formerly employed; that the process carried on with it is identical with the Jones invention, and that its primary, if not its sole use, is for mixing purposes, with necessarily incidental storage, while the Bessemer intermediate ladle was solely used for storage, with little, if any, thought of the advantages to be gained by an incidental mixing.

Discarding now all that does not bear directly upon the validity of the Jones patent, and dropping all superfluity of words, let us determine exactly what Jones has contributed, if anything, to the art of making steel. He undoubtedly found reservoirs of small size in use in which were poured from receiving-ladles enough molten metal to fill them, and from which a sufficient amount was discharged to supply a converter, usually about half the size of the reservoir. But in all these cases the fact whether any particular amount of metal was left in the reservoir was treated as a matter of indifference or accident, although there must have been necessarily some incidental mixing; and probably the metal as it ran into the converters approximated more nearly to uniformity than when it ran into the reservoir. The former methods were adequate for cupola metal, uniformity in which had been largely secured by a careful selection and breaking up of the pigs, but it had not proved a success for blast-furnace metal, except that it had been used to a very limited extent in foreign countries where the peculiar character of the iron ore had rendered it possible to carry on a direct process, although apparently by methods quite other than those employed by Jones. The principal step employed by Jones was to magnify the capacity of the reservoir about twenty-fold, provide it with a cover, and to arrange that it should not be tilted beyond a certain point, in order that a "considerable quantity" of molten metal might be retained in it for a sufficient time to accomplish a pretty thorough mixing, but little change having been made in the meantime in the size of the receiving-ladles and converters. As the reservoir was designed to hold a large quantity of metal for a considerable time it must have been covered to obviate the contents being eroded over or sculled.

As soon as this method had proven to be successful by employment at the Edgar Thompson works, and had become so well known as to attract the attention of other manufacturers of steel, it found a ready sale, was adopted by all the leading manufacturers in this country, and was sold for use abroad for about fifty thousand dollars.

It should be borne in mind that this process was one not accidentally discovered, but was the result of a long search for the very purpose. The surprise is that the manufacturers of steel, having felt the want for so many years, should never have discovered from the multiplicity of patents and of processes introduced into this suit, and well known to the manufacturers of steel, that it was but a step from what they already knew to that which they had spent years in endeavoring to find out.

It only remains now for the wisdom which comes after the fact to teach us that Jones discovered nothing, invented nothing, accomplished nothing.

We cannot better conclude this opinion than by the following extract from the opinion of Mr. Justice Bradley in *Webster Loom Co. v. Higgins* (21 O. G., 2081; 105 U. S., 580, 591):

But it is plain from the evidence, and from the very fact that it was not sooner adopted and used, that it did not, for years, occur in this light to even the most skillful persons. It may have been under their very eyes, they may almost be said to have stumbled over it; but they certainly failed to see it, to estimate its value, and to bring it into notice. . . . Now that it has succeeded, it may seem very plain to say one that he could have done it as well. This is often the case with inventions of the greatest merit. It may be laid down as a general rule, though perhaps not an invariable one, that if a new combination and arrangement of known elements produces a new and beneficial result, never attained before, it is evidence of invention.

The decree of the circuit court of appeals is therefore reversed and the case remanded to the Circuit Court for the Western District of Pennsylvania for further proceedings consistent with this opinion.

DISSENTING OPINION.

Mr. Justice WHITE, with whom concurs Mr. Chief Justice FULLER, Mr. Justice HARLAN and Mr. Justice BREWER, dissenting.

To elucidate the reasons which constrain me to dissent, it is deemed essential to give a more outline of the processes by which iron and steel were made prior to June 4, 1889, when the patent in suit was issued, in so far as such processes in some aspects concern the manufacture of steel by what is known as the Bessemer method, to which the Court now declares the patent in suit solely relates.

Into the stack of a smelting-furnace iron ore, with suitable fluxing material and fuel, was introduced. In the operation of the furnace the ore was reduced to a metallic state by the oxidizing action of carbon or gas containing carbon. This metallic iron melted in the lower part of the furnace, taking up a proportion of carbon and other ingredients, dropping to the bottom of the hearth as molten pig-iron. The earthy impurities combined with the flux, and were also melted and descended into the hearth, resting upon the top of the molten metal. The molten metal was drawn from the hearth from time to time by tapping, and the molten impurities, combined with the flux, forming a cinder, were also drawn from the hearth at a higher level. As the molten iron was tapped it was run out into molds and came to be known as pig-iron or pigs. These pigs were not of uniform composition, because of the varying quantity of the constituents contained in the ore and the chemical changes wrought by irregularities incidental to the operation of the furnace.

To make foundry-castings, pigs were selected, broken up, charged into a cupola-furnace, reduced to a molten state, and the liquid was drawn off into a receiving-ladle. From this the quantity desired was tipped into a smaller vessel, known as a casting-ladle, and was poured into the molds. Where more than one cupola-furnace was employed each was tapped and the metal poured through a groove into a receiving-ladle, common to the furnaces,

where it was held for use, and drawn as required into a casting-ladle and carried to the molds, as already mentioned.

In 1855 and 1856, Sir Henry Bessemer obtained various patents covering his discovery for producing malleable iron and steel by forcing currents of air through molten iron. The appliances described was a refractory-lined vessel, called by Bessemer a converting vessel, which came to be designated as the converter or the vessel. Without going into detail, it suffices to say that, for various reasons the method of Sir Henry Bessemer proved not to be as advantageous as had been expected. Indeed, it was not until Mushet patented a method of decarbonizing iron by completely blowing it and adding ferromanganese or spiegelstein in a molten state that the difficulty of producing steel was solved and the process of Sir Henry Bessemer was rendered practical. Despite, however, the fact that Mushet's discovery was of immense value and rendered Bessemer's conceptions a commercial success, Mushet allowed his patent-right to lapse through neglect to pay the requisite fees in the third year; and (to quote the language of the author of the article on Iron, contained in *Encyclopædia Britannica*, 9th ed., Vol. 12, p. 342)—

in consequence his name is all but forgotten in connection with his improvement on Bessemer's own process, the combination being indelibly termed "Bessemerizing."

In the manufacture of steel by the Bessemer-Mushet process two methods were followed: one termed the indirect, the other the direct. In the indirect, pigs were charged into a reverberatory furnace, for which, at a later date, a cupola-furnace was substituted. In such furnace the pigs were melted and run into ladles or reservoirs, and thence the molten iron was conveyed to the converter for the necessary treatment. Without attempting to give accurately the variations in the size and consequent capacity of cupola-furnaces and converters, it is unquestioned that the quantity of molten metal which could be drawn at a single tapping from the cupola was usually not adequate to supply a full charge to the converter. It followed that ordinarily more than one cupola-furnace was used to supply a converter, and that the tappings from such cupolas were drawn into a common reservoir or ladle, and there stored until required to be carried to the converter. Indeed, irrespective of the necessity of storing the tappings, growing out of the difference between the capacities of the vessels in question, such storage was additionally required in order that the operation might be continuous, in case of delay resulting from accident to the converter or otherwise.

In the direct process the capacity of blast-furnaces greatly exceeded that of cupola-furnaces. The molten iron was tapped directly from the blast-furnace into a number of receiving reservoirs or ladles, and carried for treatment to the converter.

On October 31, 1888, William B. Jones made application for two Letters Patent, one stated to be for a new and useful improvement in apparatus "for mixing molten pig metal," the other for a

process declared to be "a new and useful improvement in methods of mixing molten pig metal." The application for the first or apparatus patent was several times rejected, and, after various amendments, was finally allowed. This patent may be dismissed from view, as it is not involved in this controversy. The first application for the process patent—which is the patent under consideration in this case—was rejected. Thereupon a new and amended application was presented. This was also rejected, when a second amendment was made, and the application was finally allowed.

As the opinion of the Court has reproduced the specifications and claims of the patent, it is unnecessary to repeat them in detail, and therefore a mere outline of them is now given. The patent was entitled "Method of mixing molten pig metal." The primary object of the invention was stated to be—

to provide means for rendering the product of steel-works uniform in chemical composition.

It was also stated that—

my invention is not limited to its use in connection with converters, since similar advantages may be obtained by casting the metal from the mixing vessels into pigs for use in converters, puddling-furnaces, or for any other uses to which pig-iron may be put in the art.

It was further stated that—

my invention may be practiced with a variety of forms of apparatus—for example, by merely receiving in a charging-ladle a number of small portions of metal taken from several ladles or receiving vessels containing crude metal obtained at different times or from different furnaces, mixing being performed merely by the act of pouring into the charging-ladle, and other like means may be employed.

It was, however, declared that it was preferable to use the device covered by the apparatus patent, and a description of the same was set out. That device, may be thus described: It consisted of a covered tilting tank of large size, "holding, say, one hundred tons of metal (more or less)," lined so as "to retain the heat of the molten contents of the vessel and to prevent chilling thereof," with receiving and charging spouts, a gas heating appliance contained in the discharging-spout, and so constructed that, after being fully charged with molten metal, drawn from the furnaces into ladles and poured into the reservoir, as the metal was poured out for use a considerable residue would remain in the reservoir to mix with an incoming charge.

The patent embodied two claims which read as follows:

1. In the art of refining iron directly from the smelting-furnace, the process of equalizing the chemical composition of the crude metal by thoroughly commingling or mixing together the liquid-metal charge and subsequently refining the mixed and equalized charge, substantially as and for the purposes described.

2. In the art of mixing molten metal to secure uniformity of the same in its constituent parts preparatory to further treatment, the process of introducing into a mixing-receptacle successive portions of molten metal containing in their non-metallic constituents, (sulfur, silicon, etc.,) removing portions only of the composite molten contents of the receptacle without entirely draining or emptying the same, and successively replenishing the receptacle with fresh ununiform additions, substantially as and for the purposes described.

On December 2, 1893, the Carnegie Steel Company, Limited, which had acquired full title to the Jones patents, commenced the present suit against the Cambria Iron Company, for an alleged infringement of the foregoing process patent. The defenses made by the answer were substantially a

denial of infringement, and an averment of want of patentable novelty.

After the evidence for the defendant was all in and several witnesses had been examined in rebuttal, the complainant, on March 30, 1897, stated—
that at the hearing of the case he will urge infringement of the second claim only of the patent in suit.

At the close of all the evidence the complainant filed what is termed a "Petition for Disclaimer," praying that the court would receive in evidence a certified copy of a disclaimer of portions of the specifications, which on that day had been sent to the Patent Office for filing. The trial court admitted the disclaimer in evidence. The portions of the specifications covered by the disclaimer are printed in Italics in the patent as reproduced in the opinion of the Court. The disclaimer need not be further noticed at this time.

It was shown beyond question that in November, 1895, the defendant had erected at its works a reservoir of the capacity of about three hundred tons, for the storage of molten metal drawn from its blast-furnaces, the metal so stored being held in the reservoir for the purpose of treatment in the converters. This reservoir was described by a witness in the following condensed manner:

It was cylindrical in shape, with slightly convex ends, and in turning (for the purpose of pouring out the metal) it revolved upon the center of the cylinder. It is supported upon cradles of rollers and the motion is imparted to the reservoir by hydraulic cylinders.

As this case, as already stated, does not involve the Jones apparatus patent, no question of infringement of the mechanical device embraced in such patent can possibly arise. In this reservoir the molten metal as tapped from the furnaces was stored continuously and the reservoir was drawn upon with like continuity to supply molten metal for treatment in the converters. While it is not asserted that the use of the reservoir, as just stated, caused the metal stored therein to become uniform in its chemical constituents, it is conceded that the method pursued counteracted the inconvenience of sudden variations in the metal as drawn for converter purposes.

There is controversy, however, whether the defendant, in reservoiring its molten metal, irrespective of the supply and demand, intentionally retained in the reservoir a considerable residuum. From the view taken by me, however, it is unnecessary to pass on this contention, since the principles deemed by me applicable to the case will be wholly unaffected, even if it be conceded that the defendant in operating its reservoir, in filling it with molten metal and in drawing the same off for use in the converter, designedly held in the reservoir a considerable residuum of molten metal in order that the metal which was subsequently charged into the reservoir might commingle with that retained.

The cause was decided by the circuit court in favor of the complainant. The court held: That the second claim of the patent referred alone to metal direct from the blast-furnace intended to be bessemerized in a converter, and that the object was, not the obtaining, by mixing, a molten metal

substantially uniform in its chemical constituents, but the avoidance of abrupt variations between the various charges supplied to the converter. The patent was construed as not contemplating the mixing of batches of metal, that is, the filling up of the apparatus and a drawing down to a "residue" before replenishing. The gist of the Jones idea was stated to be—

the creation and maintenance of a great pool of metal between the blast-furnace and converters, through which all the incoming and outgoing metal must pass—

by which means abrupt variations were prevented, although neither a uniform molten metal nor a uniform product was thereby obtainable. Indeed, the court said:

In Jones, uniformity is a non-essential; in fact, a non-attainable attribute of product, and is a necessary non-sequens of material used.

While the court found that reservoiring was well known in the art at the time the Jones patent was obtained, and that mixing necessarily resulted from such reservoiring, it held that the Jones method was patentable, because the reservoiring known to the art contemplated storage, and not the prevention of abrupt variations; that although a mixing of the metals was of course the inevitable result of the reservoiring, such fact did not preclude the validity of the Jones patent, because prior to its grant the mixing arising from reservoiring was incidental to storage, while under the Jones method the storage was incidental to the mixing. The court said:

Now that mixing of some character took place in the ladle during these operations, that where it took place the resultant was a homogeneous average of all constituent ingredients contained, are facts to gainsay which would be to question nature's laws; but the indisputable fact remains that such mixing was accidental, eccentric, and non-systematic, and, therefore, not of a systematic, regular, functional type or for a systematic, functional purpose.

A decree was entered reciting that the patent in question was valid as to the second claim thereof; that the defendant—

by reason of the use of a certain method of mixing molten pig metal, as in the said complainant's bill set forth, has infringed the said recited Letters Patent as to the second claim thereof, and has violated the exclusive rights of the said complainant thereunder.

It was adjudged that recovery be had of the gains and profits made by the defendant and the damages sustained by complainant, and a master was appointed to ascertain the amount of such gains, profits and damages. The defendant was, in general terms, enjoined from any further infringement of the second claim of the Letters Patent and of the exclusive rights of complainant thereunder.

An appeal was taken to the circuit court of appeals. That court held that the second claim of the patent did not cover the retention in reservoiring of a considerable residuum, even though the same was designated as a dominant pool, and if it did that the method was not patentable in view of the state of the art, and that the proceedings in the Patent Office demonstrated that this was in effect conceded by Jones. It was decided that the defendant had the right to reservoir its molten metal, and that its method of doing so did not infringe the patent. The court decided that the disclaimer was not warranted by the statute, but that

[Vol. 35,

No. 3.]

in any event it was ineffective to alter the true meaning of the patent. Thereupon the decree of the circuit court was reversed.

This Court now reverses the decree of the circuit court of appeals, adopts the views of the circuit court, and in effect affirms the decree of that court. The Court expressly upholds the theory of a dominant pool, and decides that the Jones patent related, not to the obtaining of uniform molten metal by mixing in a reservoir, and a resultant uniform product, but solely to the procuring by means of reservoiring, molten metal which would not abruptly vary in its chemical constituents when drawn from the reservoir for use in a converter. The opinion of this Court now, as did that of the circuit court, expressly concedes that reservoiring of molten metal was well known in the art at the time the Jones patent was applied for, and that mixing was the inevitable result of such reservoiring, but it is decided that this fact did not operate to deprive the Jones method of novelty or to relieve the defendant from the charge of infringement.

My mind is unable to assent to the construction which the Court affixes to the patent, and as it is conceded that the method used by the defendant does not infringe, unless the patent has the import which the Court has given to it, the reasons for my dissent would perhaps be most directly made manifest by stating what seems to me to be the true construction of the patent. Doing so, however, is for the moment precluded for two reasons: 1. Because to my mind it seems that even if it be granted, *arguendo*, that the patent is susceptible of the construction which the Court has placed upon it, on the face of the opinion, the conclusion reached is wrong; in other words, the opinion of the Court to me seems self-destructive. 2. Because if the concession of the Court be accepted, that reservoiring and mixing were well known in the art, then it follows, from a consideration of the record, that the patent, as construed by the Court, was wanting in patentable novelty. That is to say, if the admissions of fact made in the opinion of the Court are right, its conclusion is demonstrated by the record to be unsound.

Let me briefly advert to the opinions of this Court and of the circuit court, to point out the reasons which constrain to the first proposition just stated. The circuit court concluded that the reservoiring of molten metal from cupola and blast furnaces for use in casting or in converters was well known to the art at the time the Jones patent was applied for. It also declared as follows:

That mixing of some character took place in the ladle during these operations; that where it took place the resultant was a homogeneous average of all constituent ingredients contained, are facts to gainsay which would be to question nature's laws.

But this was held not to establish that at the time the Jones method was patented that method as now construed was known to the art or had been anticipated, because, in the prior practice, the mixing "was accidental, eccentric and non-systematic, and therefore not of a systematic, regular, functional type, or for a systematic, functional purpose," that such mixing was incidental to storage,

[Vol. 35,

while in the Jones method storage was incidental to mixing. This Court approvingly adopts and elaborately restates these views.

Now, my reason does not enable me to conceive how, consistently with the view of the prior state of the art as to mixing and reservoiring which is admitted, the conclusion as to the patentability of the Jones method as construed can be sustained.

It would seem to be beyond question that, as it is held that the mixing resulting from the storage as practiced prior to the grant of the Jones patent, was the resultant, as stated, of a well-known law of nature, it must follow that the qualifying words "accidental, eccentric, non-systematic, and functional type or purpose" could only relate to the conduct of the persons who practiced the method prior to the Jones patent. This must be, unless it can be said that a well-known law of nature was accidental, eccentric, non-systematic and non-functional. The qualifications then applying, not to the law of nature, but to the conduct of parties, the reasoning must come to this: Although the method attributed to the Jones patent was well known to the art at the time that patent was issued, and hence it was intrinsically wanting in patentable novelty, nevertheless such method must be held to have embodied invention because the well-known practice was carried out by individuals in a varying and irregular manner. But this is only to say that while the Jones method was old, it must be treated as new because of the conduct of individuals in applying the method and their intentions. And this reduces itself to the proposition that the Jones patent as construed covered the mere intention or mind of persons. The reasoning is equally applicable to the distinction which is asserted to exist between storing and the mixing incidental thereto, and mixing with incidental storage. The mere form of expression cannot create a distinction where none exists, or destroy a law of nature. As by me it cannot be conceived that various charges of molten metal can be stored in a common reservoir without resulting mixing, it follows necessarily, by the law of diffusion of fluids, the mixing is the secondary result arising from and created by the primary act of storage. It is impossible that the secondary force can be caused to become the first and creating power by a mere collocation of words. If, then, the distinction has significance, as of course it must have, since the Court makes it the basis of its decision, it can only mean this, that those who practiced the reservoiring of molten metal before the grant of the Jones patent mainly contemplated storage, and did not in their minds take into view the inevitable mixing, which would arise therefrom by a law of nature; therefore, in the minds of the person so reservoiring the storage was the primary and the mixing the incidental consequence. But, on the contrary, as those reservoiring metal after the Jones patent must be considered to have contemplated, first, the advantages resulting from mixing, therefore, in their minds, the mixing is the principal and the storage the ac-

No. 3.]

cessory. But this is only again to say that while the Jones method was old it is to be treated as new because it covered the intention of those who stored metal for the purpose of use.

Aside from this, it seems to me the concession that the placing of molten metal in a reservoir for use as required was well known at the time the Jones patent was issued, is inconsistent with the ruling now made, that the Jones patent validly embraced the retention in a reservoir of a mass of such metal, now described by the Court as a dominant pool. The elementary import of the right to reservoir, as applied not only to molten metal, but other fluids, is the storing of the fluid for use as required, and this implies the drawing off as desired, the replenishing at will, and the keeping of such residuum or reserve supply as may be deemed best. It may not be doubted that to say that one who stores fluid for use is obliged whenever he draws any off to draw all off before replenishing, is to say that such party has not the right to reservoir. If it be meant by the Court that the right to reservoir carries with it the right to draw off or to retain at will, unless the person reserving intends to retain a residuum for a particular purpose, the reasoning reduces itself again to the proposition that the Jones patent covers, not the process described therein, but the mind and intention of the individual who may exercise the right to reservoir molten metal. That is to say, my reason does not enable me to understand how the right to reservoir can be admitted, and yet such right be at once denied by a construction of the patent which imposes qualifications on the right to reservoir, which, in effect, renders its beneficial exercise impossible. In other words, I fail to see how the exclusive right can be conferred to do the very thing which the Court admits was well known at the time the patent to Jones was issued. The conflict which my mind perceives between the facts admitted upon the face of the opinion and its conclusion is expressly pointed out by the opinion itself, where it is said:

If the contents of the mixer used by the defendant were allowed habitually to become empty in carrying out its process there would be no infringement.

That is, if in the use of its reservoir the defendant did not habitually retain a residuum there would be no infringement. But the admission that the occasional use of a residue would be no infringement concedes that the patent did not embrace the right to use a residue, for if it was covered by the patent it would be an infringement to avail of it even occasionally. Thus it must follow that the exclusive right which the Court upholds is expressly declared to relate, not to the process, but to the mere habit of the defendant.

For the purpose of demonstrating the second proposition previously adverted to, let me now recur to the state of the art as depicted by the record, in order to point out that even if the Jones patent embodied the process which the Court now attributes to it, that process was wanting in patentable novelty. In doing this, for convenience, the subject is thus divided: (a) the use of molten

metal drawn from cupolas for foundry purposes, before the invention of Bessemer, as well as the foundry practice and the bessemerizing practice by the indirect process after such invention and before the grant of the Jones patent; (b) the direct process of making steel from blast-furnace metal prior to the grant of the Jones patent.

FOUNDRY AND INDIRECT BESSEMER PRACTICE BEFORE THE GRANT OF THE JONES PATENT.

1. *The Whitney Car-Wheel Practice.*—At the Whitney car-wheel works in Philadelphia, commencing in 1847, remelted pig metal from several cupola-furnaces was tapped at intervals into a large reservoir-ladle, having a capacity of from twelve to fifteen tons. From this the molten metal was poured into charging-ladles having a capacity of but six hundred pounds. A considerable residue was always maintained in the reservoir-ladle. The principal purpose, as testified to by witnesses having personal knowledge of the subject, was to secure, as a consequence of the mixing resulting from the reservoiring, the production of a practically uniform product. Excerpts from the testimony of John R. Whitney contain a clear statement on the subject:

When the (large) ladle was nearly full we began to pour from it into smaller ladles, each one of which held enough for one wheel; if it was an ordinary-size wheel it held enough for two wheels; and if the wheels were smaller ones it held enough for two or three. As that drew the molten iron from the ladle and the iron continued to melt, the ladle was constantly being filled from the cupolas, and it was kept full until all the iron charged in the three cupolas was melted and the bottoms dropped. Then the iron was continued to be poured out of the large ladle until it was all used, these two methods making the uniform mixture; that is, we mixed it in a solid state, first by our charges and then in the molten state in the large ladle.

As the mixture (of selected iron) was charged into each cupola, as I have stated, it was made up of iron from various furnaces, some iron having one quality and some another. As it melted in each cupola, it did not all melt at the same time, and if we had drawn it directly from the cupola into the small ladles from which we poured the wheels, one wheel might have been poured out of very hard iron, another wheel out of very soft iron, and so every shade between. There would have been no uniformity in our work. But by taking it from the three cupolas, all melting the same charges of iron, and collecting them in a molten state, the inequalities of melting were all overcome and a uniform product produced.

2. *The Wheeling Foundry Practice.*—Kirk on *Foundry of Metals*, 1875, thus describes a foundry practice, (italics not in original):

In melting iron I should recommend melting it hot, and as fast as possible. A quantity of molten iron should be kept in the cupola or in a large ladle, so as to give the different brands of iron a chance to mix. In most all the foundries at Wheeling, W. Va., the cupolas are never stopped in from the time the blast is put on until the bottom is dropped. A large ladle is set on trestles in front of the cupola, in such a manner that the iron can run into it from the cupola and be poured out into the smaller ladles at the same time. The iron is all run out of the cupola as fast as it is melted, and is mixed in a large ladle. I think this is a good way of mixing iron. See alloy.

3. *The Altoona Practice.*—At the Altoona wheel-works of the Pennsylvania Railroad, from 1871, the cupola metal was designedly stored and mixed. The early reservoir-ladle, of seven tons capacity, received the metal from two cupolas, and was thus described:

A. The ladle turns on two transoms and has chains leading from these transoms down to the hydraulic cylinder shown on the drawing, one chain being wound in one direction on one transom and other being wound in the other direction on the other transom, and the two chains being connected at opposite ends of the piston-rod.

In describing the regular way of working each day the witness said, (italics not in original):

In the first place each cupola is charged with about forty tons of metal. We charged about forty tons in each cupola; then

[Vol. 52, No. 8.]

after we have this done we put the blast on and begin to melt, and as soon as now the lad in the cupola is filled up with molten metal we tap it out into the receiving ladle or reservoir, which fills the reservoir about one-half full, then we stop the cupolas up again until the iron raises to the eye-hole, then they are tapped again, and this second tap generally fills the reservoir; then after the reservoir is full, we begin to pour the metal out into smaller ladles, then send it around to the molders for pouring into the wheel-molds.

The custom was to empty the receiving ladle about one-half; then hold the remainder of iron in the reservoir until the cupolas were ready to be tapped again; and after the reservoir is full we start and pour out into the smaller ladles again. The receiving-ladle at all times is kept about one-half full, and it is this full when we tap the metal ladle it from the cupola.

In the *London Engineering* for 1877, describing the practice pursued at Altoona, when a ten-ton receiving-ladle was used, it was said:

It was found advisable to employ a ladle of so large a capacity because by doing so a more complete mixture of the different irons is effected than would be the case if a smaller vessel were employed.

And the methods of using cupola metal for foundry purposes above described were early applied to making Bessemer steel by the indirect process. The following excerpt from the testimony of a witness clearly states the subject:

A. I. Holley, who built the Troy works, and made his first conversion in 1855, introduced into this original plant a tipping accumulating-ladle resting on scales. This ladle was patented by Bessemer in 1858, English Patent 186, alluded to in the previous answer, but apparently was an American invention. It was introduced in some form or other in all the American works, and was used almost always in duplicate, holding about two heats each, or many cupola-tappings. In the last works built in St. Louis by Holley, in 1876, there were three of these ladles. In all American works these ladles were turning or tipping ladles, and were placed on scales to weigh the converter charges.

In 1877, describing the Vauxhall works, a plant designed and erected under Mr. Holley's supervision, that gentleman said, (*London Engineering*, Vol. 23, 1877):

The cupola-ladle facilitates the distribution of metal to the vessels. They form a reserve which enables the melting-department and the converting-department to work independently of each other within limits. This advantage was not appreciated fully until the large productions of the last few years were attempted. Should any delay occur in melting, or preparing a vessel, or from any cause, the melting-department keeps right on, for these ladles will hold an vessel charge, which may be stored and converted when the converting-department is ready for them. Cast-iron will "live" in these tipping-ladles, when covered with charcoal, for several hours. But it is necessary to put these ladles upon weighing-machines, so that either uniform vessel charges may be run out, or so that special charges may be proportioned to each charge as are run out.

These ladles were variously named. Holley called them cupola-ladles, interposed ladles and reservoirs. Hunt described them as "intermediate accumulating-ladles."

A witness thus testified respecting the extent of use in this country of the receiving-ladle as follows:

Early American steel-works, commencing with Troy in 1854, Pennsylvania in 1857, Cleveland in 1858, Cambria and Union in 1871, Martin Chicago in 1873, Jones and Bessemer in 1875, Edgar Thompson and Lehigh in 1876, and Vauxhall in 1876, used receiving-ladles, two in number, holding about two heats each, with the exception of Bethlehem, which used a single ladle on a car to mix taps from four cupolas, and Vauxhall, which used three receiving-ladles, holding two heats each. These ladles were used for storing and measuring the heats.

It is shown that from 1870 to 1880 the capacity of the accumulating-ladle used at the works of the defendant was 23,000 pounds, and the converter charge 15,000 pounds, leaving 12,500 pounds in the ladle after a charge was supplied to the converter. The cupola-taps of from 4,000 to 6,000 pounds passed into and filled such ladle.

Describing the mode of use of the ladle, Price, a witness, said:

It was the custom to have in the ladle an amount of metal equal to the difference between the converter charge and the

[Vol. 52, No. 8.]

full ladle capacity. . . . This ladle was again filled to its full capacity by retapping the cupola.

The metal from the several cupolas necessarily varied from time to time considerably, both in chemical and physical conditions; at those the metal being such from one or two of the cupolas that in themselves they would be unfit for converter use. But by the means which was effected by the intermediate ladle, the metal from this one, or the two, cupolas, would be averaged with the better-adapted metal for converting from the others.

Speaking of the beneficial effects resulting from the use of the accumulating-ladle at the works of the defendant, another witness (Cabot) said:

The mixing of cupola metal at Cambria was accomplished by the tapping of a number of cupola-furnaces into one large receiving-ladle, from which converter charges were poured off, and the supply in this ladle again increased by further tapping. The practice at the Vauxhall steel works was similar to that. The purpose was to obtain a supply of metal for the converters to equalize the different streams of metal from the different cupolas, and that was its effect. It accomplished that.

Yet another witness (Hunt) declared:

It was recognized as one of the great features of the intermediate ladle, that it made the work so much more uniform in results from mixture or evening up of the various grades of pig-iron used.

What distinction can be drawn between these methods and the patent as now construed? This Court and the circuit court did put aside the Whitney method on the ground that it provided for obtaining absolute uniformity of product, while the Jones method was held to provide simply for avoidance of abrupt variations. While it is clear that a method which had for its purpose merely the prevention of abrupt variations would not necessarily include one for the obtaining of a uniform product, how a method of reservoiring molten metal as such metal is produced in the furnace and drawing it off from the reservoir for use, which produced uniformity of product as the result of the reservoiring, can be said not to have embraced the prevention of abrupt variations, is to my mind absolutely unthinkable, since the greater must necessarily include the lesser. For, of course, as there cannot be abrupt variations in the constituent elements of a molten metal which is uniform, it must follow that a process of reservoiring which in the continuous operation of a plant will obtain a uniform metal must necessarily exclude abrupt variations in the quality of the metal.

The Court now, in addition, disposes not only of the Whitney practice but of the others to which reference has just been made, by certain general considerations which it is held applies to them all. These considerations are, first, an assertion that although all such practices included reservoiring and the incidental mixing arising therefrom, none of them contemplated mixing as a necessary and inherent attribute, and none of them embraced the retention in the reservoir of a considerable mass of metal, a dominant pool, as a part of the process of reservoiring; and, second, as the practices in question related to molten metal drawn from cupolas, therefore they did not establish that reservoiring and mixing were known to the art so far as concerns the molten metal drawn directly from blast-furnaces.

The first proposition, it is submitted, is absolutely in conflict with the express and uncontroverted proof in the record, as manifested by the references which I have already made. Let me

[Vol. 52, No. 8.]

recur to the practices under consideration to show that this is the case. Take the Whitney practice as testified to by Whitney. After saying that withdrawals were not made from the reservoir until "it was nearly full," and describing the drawing off of the molten metal from the reservoir, he said:

And (as) the iron continued to melt (in the cupolas) the ladle was constantly being filled from the cupolas, and it was kept full until all the iron charged in the three cupolas was melted and the furnace dropped.

The witness thus clearly showed not only the constant retention of molten metal in the reservoir, but that such retention was recognized in the practice as essential to secure "desired uniformity of molten metal." I cannot see how there can be doubt on this subject, in view of the fact that the witness added:

If we had drawn it (the molten metal) directly from the cupola into the smaller ladles from which we pour the wheels, one wheel might have been poured out of very hard iron, and another wheel out of very soft iron, and so every shade between. There would have been no uniformity in our work. But by taking it from the three cupolas, all melting the same charges of iron, and collecting them in a molten state, the inequalities of melting were all smoothed and a uniform product produced.

Take the wheel-foundry practice as portrayed in Kirk's publication. The statement is made that—"a quantity of molten iron should be kept in the cupola, or in a large ladle, so as to give the different brands of iron a chance to mix."

Again:

The iron is all run out of the cupola as fast as it is melted, and is mixed in a large ladle.

The publication thus clearly pointed out the advisability of retaining a residuum in the cupola or in the reservoir, for the purpose of better mixing.

Recurring to the Altoona practice, doubt on the subject seems to me to be in reason impossible. It is not gainsaid that such practice embraced reservoiring and mixing. It cannot, it is submitted, be affirmed that it did not embrace the retaining in the reservoir of a large residuum of metal for the express and necessary purpose of making the mixing more perfect, if the proof as to the practice pursued is not wholly disregarded. What was that practice? When the metal in the cupolas began to melt, it was drawn off into the reservoir until the reservoir was half-full; then the withdrawals from the cupolas were stopped. But the metal in the half-full reservoir was not, however, then made use of. Why was it not so used, although ready in the reservoir? The answer is, because it was deemed best, in order to obtain beneficial results from mixing, to hold the half-full reservoir for a subsequent tapping therein from the furnace, of a quantity of molten metal sufficient to fill the reservoir. Only when the reservoir was thus filled did they commence to draw the metal therefrom, and when by such use the quantity in the reservoir was reduced to about one-half, then the drawing off was stopped, so as to retain about the one-half until there was a further replenishing from the furnace, and thus the operation continued. Now, by a mere affirmation, it can be held that the process which has just been described did not contemplate the constant retention of a considerable residuum in the reservoir, is to my mind inexplicable. Let me quote again

from the record the uncontradicted testimony as to the practice in question:

The custom was to empty the receiving-ladle about one-half; then hold the remainder of iron in the reservoir until the cupolas were ready to be tapped again; and after the reservoir is full we start and pour out into the smaller ladles again. The receiving-ladle at all times is kept about one-half full, and it is this full when we tap the metal into it from the cupolas.

The irresistible conclusion thus arising from this proof is, it seems to me, rendered if possible clearer, when it is recalled that as early as 1877 the *London Engineering*, in a reference to this practice, declared:

It was found advisable to employ a ladle of so large a capacity, because by doing so a more complete mixture of the different irons is effected than would be the case if a smaller vessel were employed.

And what has just been said applies equally to the practice of making Bessemer steel from cupola-furnaces. That the excerpts which I have given on this subject clearly show that mixing by the use of a residuum was the result of the employment of the accumulating-ladle, and a result that was well known and intended, it seems to me cannot be gainsaid. How the Jones method, as construed, can be declared to have been novel—because in cupola metal there was no variation requiring mixing—in face of the fact that the very patent which is sustained, in various forms of expression, expressly declares that such variation exists, is not by me comprehended.

Besides, the proposition involves an unsound deduction, since it in effect not only disregards the fact that the practices in question were availed of with the avowed purpose of correcting the inequalities found to exist in cupola metal, but also the erroneous assumption that there could be patentable novelty in merely applying to blast-furnaces the well-known practices as to cupola metal.

It may well be conceded, without affecting the case, that the variation is greater in metal drawn from blast-furnaces than in that drawn from cupolas, but this mere difference in the degree of variations between the two affords no ground for construing the Jones patent in such a way as to cause it to cover the well-known prior methods.

Nor does the example given in the opinion of the Court for the purpose of illustrating the difference which is found to exist between the practices to which I have referred, and the Jones patent, as now construed, enable my mind to discover the difference. The Court says, (italics mine):

Let us imagine a reservoir containing, say, three quarts, and filled with one quart each of three liquids of different constituent parts, and withdrawers for further treatment at the rate of one or two quarts at a time. Necessarily there would be some incidental mixing, but it would occur at once that the main object of the reservoir was a retention of a sufficient quantity of the mixture to supply the receptacle for further treatment, and if no necessity existed for a longer retention of the liquid in the reservoir, it could be very quickly emptied by two discharges into the receiving vessel. Now, let us substitute for this reservoir a tank of, say, sixty quarts, into which the liquids of different constituent parts are poured in at one end and from a multitude of receptacles, and discharged at the other end after remaining a certain time in the tank, and that this tank could not be tilted so far but what a quantity of liquid would be left in it amounting, say, to half its capacity. Now, if there be no distinction between these two operations, there would be little left to the Jones process, the very novelty of which consists in the size of the tank relative to the ladles and the mixing of the various liquids poured into it before they are withdrawn.

In the first place, this example fails to notice the fact that in the accumulating-ladle the metal was received from several—in some instances as many

[Vol. 60, No. 3.]

as four or five cupolas—and that in practice a residuum was constantly maintained, and for the purpose of mixing, and that these ladles could not be drained of metal unless there was an intention to do so. The only distinction afforded by the example is that resulting from the difference in sizes of the two supposed receptacles in which the mixing was accomplished. But this would reduce the patentable novelty in the Jones process to the size of the reservoir. Indeed, it is so expressly stated, since in the opinion it is declared that—

there would be little left of the Jones process, the very vitality of which consists in the size of the tank relative to the ladles and the mixing of the various liquids poured into it before they are withdrawn.

The mixing having been disposed of by what I have already said, it follows that the "very vitality" of the patent is found to be the size of the tank relative to the ladles, which in reason is a direct abandonment of the whole theory of a dominant pool previously expounded as the source of vitality in the patent. But the size of the reservoir—called by the Court a tank—relative to the capacity of the plant, is clearly shown not to have been novel, by what has been previously said, and will be further demonstrated beyond peradventure by the consideration which it is now proposed to give to—

THE MANUFACTURE OF BESSEMER STEEL BY THE DIRECT PROCESS.

The use of the direct process for bessemerizing, it would seem, was at once resorted to on the Continent of Europe, and there is testimony in the record giving rise to the inference that the greater uniformity of the ores used in the blast-furnaces on the Continent caused such processes to be there at once quite successful. However, it may not be doubted that on the Continent the use of a reservoir or accumulating-ladle sometimes obtained, and the advantage which it afforded of bringing about a desirable mixture of the metals from several furnaces was known. Thus Kohn, in the *Journal of the Iron and Steel Institute*, 1871, speaking of the practice at Terrenure, in France, said:

The iron is first run into a ladle, as explained by Mr. Monette, and so taken to the converter. The ladle is brought to the back of one furnace, and half-filled; it is then run to the next furnace and filled up. In this way the Terre Noire Company always obtains a mixture of the metals, and therefore the greatest regularity is secured through the rest of the work. The furnaces are kept in regular working order, and by carefully managing the charges of the blast-furnaces and watching them as much as possible, the practical result is that there is no inconvenience as regards the furnaces themselves in tapping frequently. The same thing is done at Mr. Schneider's plant at Creusot, but he believed they do not there go so far as to mix the iron.

In England, the direct process was not made use of until about 1877, and it is known that this largely resulted from the fact that the Bessemer plants in the early use of the process were not connected with blast-furnaces.

In this country, though the manufacture of Bessemer steel was commenced in the early sixties, and in one or two of the early experimental plants a brief use was made of direct metal, the indirect process was in general use until the year 1883, when the first large plant equipped for direct use of blast-furnace metal began operations at the new South

[Vol. 60,

Chicago works of the Illinois Steel Company, and later in the same year the Edgar Thompson works (the Carnegie Company), with five new furnaces, also commenced such work. These plants were still producing steel by the direct process, with the use of the accumulating-ladle when the Jones patent was granted in 1880, and it was not until the year 1886 that a large storage-tank was installed at the South Chicago works.

A number of patents having relation to the making of steel by the Bessemer direct process were from time to time granted before the Jones patent was issued, and I shall now notice the most important of such inventions, as also some other publications embodied in the literature of the art.

In the British patent to Deighton of 1873, the purpose of the inventor, among others, was declared in the specifications to be to keep a steel-works plant or apparatus in nearly uninterrupted work, thus very considerably increasing the production of such plant. It was said:

Instead of manufacturing Bessemer iron or steel from pig-iron which has to be melted in cupolas, my invention also consists in taking the molten metal directly from the blast-furnace or the converter, in which case I prefer to arrange the Bessemer plant in a line at a right angle to a row of two or more blast-furnaces, and place a vessel to receive the molten metal tapped from two or more blast-furnaces to get a better average of metal which will be more suitable for making Bessemer steel or metal of uniform quality, the vessel or receiver being placed on a weighing-machine so that any required weight may be drawn or tapped from it and charged into the converter.

The apparatus was then described in detail, and consisted of blast-furnaces, arranged in a line, with channels from each furnace to a common reservoir or mixer, and with a connection from the mixer to a converter, so that the molten metal in running from the blast-furnaces might go into the reservoir and be mixed, and might be drawn off as desired to the converter. It was stated that the receiving vessel—

is placed low enough to give fall for the molten metal to flow from the blast-furnaces to this reservoir, which forms a receptacle for mixing the molten metal from two or more of the smelting-furnaces. From the reservoir in the mixed molten metal is tapped and flows down the vertical through a into the converter. By placing the vessel on a weighing machine it can be readily ascertained when the exact quantity required has been tapped from it into the converter.

In 1885, a few years prior to the grant of the Jones patent, two United States patents were issued to James P. Witherow, 1, for Apparatus for the Manufacture of Iron and Steel; and, 2, Steel Plant Appliance, which patent showed a blast-furnace, an intermediate storage vessel of large size and a converter. In brief, the purpose of the Witherow reservoir apparatus was to receive and store the molten metal for the purpose of preventing the detention incident to the necessity of discharging the contents of the blast-furnaces when there is no converter ready to receive it. The advantage of the large storage-receptacle was thus stated in the specification of one of the patents:

The metal is usually tapped from a blast-furnace once in every six hours, and the quantity thus run is many times in excess of the charge of a converter. . . . The charge of a converter is from one to five tons, and in the case of a blast-furnace usually runs from ten to fifty tons. . . . The time between charges of the converter is usually twenty minutes and upward, and the metal from the furnace must be kept in condition to be tapped from time to time into the converter as needed.

The evidence establishes that the Deighton and Witherow reservoirs were, each, of a capacity of one hundred tons.

No. 3.]

Commenting, in June, 1877, upon the merits and demerits of the use, then just commenced in England, of direct metal—that is, the conversion of molten metal direct from the blast-furnace, without remelting in a cupola or storing it in a large reservoir—A. L. Holley said, (Italics mine):

It has not yet been practicable to work the blast-furnace with sufficient regularity to realise approximately the theoretical advantages of the direct process.

Fourth. The obvious remedy is to mix a number of blast-furnace charges, so as to reduce the irregularity to a minimum. Two systems of doing this are on the eve of trial: the one is simply mixing in few charges in a tank (that the metal will be drawn out before it cools); the other is to store a larger number of charges in a heated tank—that is to say, in an immense open-hearth furnace.

The first of these two systems of mixing would seem to be that embodied in the following portion of Mr. Holley's description of the West Cumberland practice:

In order to get a more uniform metal, Mr. Stiles is about trying the experiment of placing a twenty-ton ladle on a hydraulic lift at the "A" pit, so arranged as to store, mix and pour, say, three six-ton to seven-ton blast-furnace taps, or to mix blast-furnace and cupola metal. I doubt this body of metal will "live" if the ladle is thickly lined and not covered. Mr. Stiles has another object also; tapping half or a third of a vessel heat out of the blast-furnace—in other words, tapping so often—wears out the tap-hole more rapidly; slag gets into the walls and weakens them. It is preferable in every way, as blast-furnace men well understand, to tap a full hearth. At the same time improvements in working the furnace are gradually developing. More care is taken as to the selection of ores, the size of ore and limestone, the distribution of materials in the furnace, the temperature of the blast, and all elements of uniformity.

Uniform results in the Bessemer department can hardly be expected, unless a number of blast-furnace charges are mixed. This would seem to be the theoretical solution of the problem.

The second of the two systems of mixing is undoubtedly the one then being erected at Moss Bay, England, viz., a sixty-ton reverberatory coal-fired furnace or two forty-ton furnaces. The ladles of blast-furnace metal were to be "tapped out into the large reverberatory furnace," in which "it is the intention to store and keep hot some sixty tons of iron from all the blast-furnaces." This method, for some reason not stated, perhaps an economical one, was not successful. Mr. Holley, in the article just noticed, referring to the arrangements in connection with the use of this "large furnace," said:

The complex manipulations due to the arrangement described seem likely to take unnecessary amount of time and labour.

After reviewing the practice in the various English and Continental steel-works using direct metal, Mr. Holley summed up his conclusions, and recommended the American works to continue for the present to select and remelt the pig metal, and continue their efforts for some time "in the preliminary department of the direct process—to increasing our uniformity of blast-furnace working and product." We excerpt the following passages from the conclusions contained in the report:

Fourth. But if the storage of a large quantity of iron in a reverberatory furnace or other reservoir should prove successful, then a few blast-furnaces making even an irregular product, and, if necessary, working in connection with cupolas, would largely economise the Bessemer manufacture.

In fact, this mixing of irregular irons on a very large scale, thus avoiding the expensive niceties of ore selection and the necessity of many furnaces, is the theoretical key to the situation. When the way to its successful adoption is demonstrated the direct process will undoubtedly have great advantages, even over the present practice on the Continent, which employs many ganiferous ores. But until this large-scale mixing is developed it should not appear that the use of our comparatively irregular blast-furnace and part cupola metal can result in any substantial saving.

But the mixing problem is not such a difficult one. A small amount of flame spread over a large surface of metal should

certainly keep it hot for a long time, seeing that the metal will keep hot in a ladle exposed to air for an hour or more. And should there be any trouble about stopping the tap-hole in a large storage-furnace, it would not be a very difficult or expensive matter (considering the Patent revolving-hearth experience) to tip the whole hearth to pour a charge.

Without stopping to comment in detail upon all the matters just referred to, there can be no question that they demonstrate that if the vitality of the Jones patent depends upon the size of the reservoir, it was clearly anticipated. They also further establish that the advisability of the use of a large reservoir for the purposes of storage and mixing was well known, and that it was deemed to be an obvious and desirable expedient is also apparent.

It is not denied that the Deighton and Witherow patents each provided for a reservoir, the former (Deighton) laying stress upon the advantages resulting from the mixing in such reservoir. Both patents, it seems to me, in effect contemplating as they did the continuous operation of the plant and in view of the relative capacities of the furnace or furnaces, the reservoir, and the converters, necessarily embraced the presence in the reservoir of a considerable residuum, without which residue the proposed continuity was impossible. As it is to me apparent, I do not stop to refer to the testimony showing that this must necessarily be the case. The argument that the Deighton reservoir had no cover, and therefore it is not the Jones process, ignores the fact that Jones in his process patent does not provide for the operation of his method in a covered receptacle, but, on the contrary, in the specifications of that patent, it is declared that the process may be carried on in a charging-ladle, an uncovered receptacle. Further, it is to be borne in mind that the record overwhelmingly establishes that it was a well known expedient to cover a ladle or other receptacle for molten metal when the metal was required to be retained longer than the customary time. The inappositeness of the suggestion that the Deighton patent ought not to be given any weight as showing the state of the art, because the patentee allowed the patent to lapse for the non-payment of fees, cannot be better illustrated than by this case, when it is recalled that the patent to Mushet, which made bessemerizing commercially practicable, was allowed to lapse because the Patent Office fees were not paid.

The demonstration of want of novelty in the patent as construed which arises from the previous considerations entirely disposes of the case, as it is, as already observed, conceded that unless the patent means what it is now held to mean, there was no infringement by the defendant. It is to me equally clear, however, that even if the state of the art be, *arguendo*, put out of view, the patent cannot be held to signify what it is now decided to mean, & without repudiating the true meaning of the patent, which is—properly deducible from the proceedings in the Patent Office, that is, the file-wrapper and contents, and without refusing to give effect to the express declarations and admissions of the patentee (Jones) as to the significance of the patent, which is also shown by the proceedings in question; and, & without misconceiving and mis-

constraining the patent. Let me briefly demonstrate these propositions.

As I have said at the outset, the application for the patent in suit when first made was rejected by the Patent Office, on the ground of the prior state of the art, as evidenced by the Witherow patents and the Kirk publication. An amended application was thereupon filed, which beyond all question eliminated from the patent all claim to an exclusive right to reservoir or store the molten metal. When this amendment was presented to the Patent Office, counsel for the applicant submitted a written argument to demonstrate the patentability of the method covered by the amended application, in which no reference whatever was made to the importance of a residue, whether of small or considerable size, but the purpose of the inventor was thus declared, (*Italics mine*):

To have a receptacle capable of holding metal in a molten condition, into which metal it may be, from several blast-furnaces, is run from time to time and from which metal is drawn for treatment in the converters, or otherwise, as required. This continuous pouring into and drawing out of a common receptacle produces such a mixture of the charges as results in a uniform average quality of metal, whether treated in the converters or used for casting without such treatment, as is very desirable, but has hitherto been found unobtainable.

But the amended application was rejected, and the Examiner—evidently having in mind the statement in the argument of counsel above referred to—called the attention of the applicant to the fact that the continual pouring into and drawing out of the molten metal to produce a mixture was anticipated by the Kirk publication. The Examiner said, (*Italics mine*):

The process, as now claimed, seems to be fully met by the description in Kirk's metal-founding, heretofore referred to, which states that the metal is run continuously from the cupola and mixed in the ladle, from which it is tapped into the smaller ladle. See also the additional references of British patents No. 122, Brennan, March 22, 1891, page 2, lines 25-26, and No. 1,225, Stewart, May 12, 1892, page 2, lines 2 and 10.

When it is borne in mind that the Kirk publication thus referred to provided expressly for a continuous inflowing and outdrawing of the metal, and besides expressly said—

a quantity of molten metal should be kept " " " " as as to give the different brands of iron a chance to mix—

the conclusion cannot by me be escaped that the Examiner pointed out to Jones that the conception of a continuous inflow and outflow, and the keeping of a residue for the purpose of mixing, was not patentable.

The presumption cannot be indulged in that the amendment was not intended to obviate the objection on account of which the Patent Office had rejected the application, and, moreover, it cannot be assumed that the Patent Office issued the patent for a method which it declared was not patentable. But now the patent is construed by the Court as covering the continuous flowing into and withdrawal from a reservoir of molten metal, and as alone referring to the prevention of abrupt variations in the metal drawn from the reservoir for use in a converter, while Jones himself declared to the Patent Office that the patent as amended related to metal drawn (from a reservoir) for treatment in a converter or otherwise, as required. Besides it was expressly stated that what the patent contemplated was the production of a uniform

quality of metal, intended for further treatment in the converters or to be used for casting without such treatment. It is submitted that this demonstrates that the construction now given by the Court to the patent is directly repugnant to the meaning which Jones affixed to it, and besides is in conflict with the ruling of the Patent Office, in which Jones acquiesced, and upon which the patent was issued; and, therefore, that the construction which the patent now receives amounts, it seems to me, to a grant by judicial decision of a new and different patent from that which the Patent Office allowed.

Conclusive as is the view just stated, it is made, if possible, more so if the correct construction of the patent be ascertained. This it is proposed to demonstrate by an analysis of the patent as originally applied for, by a consideration of the amendments made to it, and by its text in its final form. Considering these matters, it will, I think, appear that the patent was not, as now held to be, solely one for the prevention of abrupt variations in the metal drawn from the receptacle for use in a converter. On the contrary, the true purport of the patent was this and this only: the selection of separate portions of molten metal, pouring the same into a reservoir, mixing such aggregated portions of molten metal thoroughly until it, the commingled metal, became uniform, so that the equalized metal might be used, not alone in the making of steel in a converter, but in any other process of making steel, in a foundry, or in any other mode where a uniform product was desired. Having thus provided for equalizing the contents of the reservoir when filled with selected metal and mixing had been accomplished, the patent contemplated that this equalized molten metal present in the reservoir should be drawn off for any desirable purpose down to an undetermined residue, so that when a fresh supply of selected metal was charged into the reservoir the metal thus newly supplied might be mixed with the residuum and thus not only a further supply of equalized metal might be obtained, but also, as a result, abrupt variations between the freshly-equalized metal and that of the preceding batch discharged from the reservoir, would be avoided.

To demonstrate the correctness of this construction, which, as already shown, was undoubtedly the view taken by the Patent Office, let me come to consider the application for the patent, the amendments and the patent as granted.

The application, as originally filed, contained a statement of the primary object of the invention, which is excerpted in the margin.*

*The primary object of the invention is to provide means for insuring uniformity in the product of a Bessemer-steel works or similar plant, in which the metal from more than one (subsequently amended to read "one or more") blast-furnace is employed to charge the converters. The product of the different furnaces, or of the same furnace at different times, varies in quality, the variation depending on the kind of ore employed, and on many other conditions well known to those skilled in the art, so that when the converters are charged at one time with the output from one furnace, and at another time with the output from another furnace or furnaces, the manufactured steel lacks uniformity in grade. To avoid this I employ suitably constructed reservoirs or vessels, into which the molten metal from

This was followed by a statement of the secondary objects designed to be attained, as follows:

My invention, however, is not limited to its use in connection with converters, since similar advantages may be obtained by casting the metal from the mixing vessel into pigs for use in converters, puddling-furnaces or for any other use to which pig-iron may be put in the art.

A description was then given of the apparatus, which it was previously stated had been invented "for practicing my invention," and the mode of operation of such apparatus was stated. The claim read as follows:

The process hereinbefore described, which consists in storing charges of molten metal in a covered receptacle provided with a heat-retaining lining, removing portions only of the molten contents of the said receptacle without entirely draining or emptying the same, and successively replenishing the receptacle with fresh additions of molten metal, whereby the character of the several charges of metal so treated is equalized; substantially as described.

Considering the application as thus made, what support does it lend to the theory now announced that it was the purpose of the Jones invention merely to prevent abrupt variations between each charge of metal drawn from a reservoir for treatment in a converter? Such purpose is nowhere declared, unless it be inferred from certain statements in the patent descriptive of the mode of operation of the appliance covered by the apparatus patent, to which, hereafter, I shall more particularly advert. The conception that the patent solely related to abrupt variations in metal drawn from a reservoir and supplied to a converter, is absolutely excluded by the fact that the secondary object is pointed out to be to secure a pig metal so uniform in its chemical constituents that it might be used "in puddling-furnaces or for any other use to which pig-iron might be put in the art." It cannot be conceived that the patent provided for making the metal uniform in the reservoir, and, by the same language, provided merely against the occurrence of abrupt variations in the equalized metal when drawn off to a converter. If made uniform, there could not, in the nature of things, be abrupt variations. It being then certain that the process patent, as originally filed, in and of itself not only contained even no intimation of the claim which the Court now attributes to the patent, it must follow that if the patent covered such a claim, it was one not in the mind of Jones, but must have been in some way evolved in the passage of the application through the Patent Office.

This original application, as I have said, was rejected by the Patent Office, as being "completely anticipated" by the Witherow patents, and reference was made to the Kirk publication.

To meet this objection a change was made by which the assertion of an exclusive right to store

the blast-furnaces is put, the vessels being of proper capacity to hold a considerable charge of metal from a single furnace, or from a number of furnaces, and being adapted to retain the metal in a molten state for sufficient time to enable the different charges to mix and become homogeneous. The advantage which I then obtain is securing uniformity and homogeneity in the total product will be readily understood by those familiar with the operations of a steel-works and the frequent loss which is caused by the lack of such uniformity. Such apparatus possesses also an additional advantage in that it makes it possible to dispense with cupola-furnaces for remelting the pigs preparatory to charging the converters. The metal may be tapped from the blast-furnaces into ladles or trucks, carried to and discharged into the mixing reservoir or vessel, and there retained in a molten state until sufficient metal has been accumulated to charge the converters.

charges of molten metal was eliminated, the amendment being as follows:

The process hereinbefore described, which consists in treating successive charges of molten metal into a covered receptacle provided with a heat-retaining lining, removing from time to time from said receptacle for subsequent treatment a portion only of its molten contents, and successively replenishing such receptacle with fresh additions of molten metal, for the purpose of equalizing the character of the several charges of metal drawn therefrom, substantially as described.

Accompanying this paper was the argument of the attorney, already referred to, in which it was expressly declared, as has been seen, that the patent related to uniformity of molten metal for further treatment in converters, or otherwise; that is, as declared in the argument, the obtaining of a metal of such uniform quality that it might not alone be used in converters, but might be "used for casting without such treatment."

As the application, as amended, was asserted to embody a claim for the continuous operation of a plant by reservoiring metal, by inflowing and outflowing, with mixing, a method construed by the Patent Office as identical with that described in the Kirk publication, the patent, as already stated, was again rejected. It was again amended, and, as thus finally amended, the patent was allowed. The new amendments consisted, first, of a substituted statement of the primary object of the invention, which is excerpted in the margin.* It will be observed, from the concluding sentence in the first paragraph, that it was clearly implied that the applicant deemed that inequalities were present in cupola metal as well as in blast-furnace metal.

There was substituted for the single claim as

*The primary object of my invention is to provide means for rendering the product of steel-works uniform in chemical composition. In practice it is found that metal tapped from different blast-furnaces is apt to vary considerably in chemical composition, particularly in silicon and sulfur, and such lack of uniformity is observable in different portions of the same cast, and even in different portions of the same pig. (Here follows table of analyses said to have been made of metal contained in different ladle charges from one cast of a blast-furnace.) . . . The consequence of this tendency of the silicon and sulfur to segregate or form pockets in the crude metal is that the product of the refining process in the converters or otherwise is like manner lacks uniformity in these elements, and therefore of ten causes great inconvenience and loss, making it impossible to manufacture all the articles of a single order of homogeneous composition. Especially is this so in the process of refining crude iron taken from the smelting-furnace and charged directly into the converter without remelting in a cupola, and, although such direct process possesses many economic advantages, it has on this account been little practiced.

For the purpose of avoiding the practical evils above stated, I use in the refining process a charge composed not merely of metal taken at one time from the smelting-furnace, but of a number of parts taken from different smelting-furnaces, or from the same furnace at different casts, or at different periods of the same cast, and subject the metal before its final refining to a process of mixing, whereby its particles are diffused or mingled thoroughly among each other, and the entire charge is practically homogeneous in composition, representing in each part the average of the unequally diffused and segregated elements of silicon and sulfur originally contained in each of the several parts or charges. By proceeding in this way not only is each charge for the refining-furnace or converter homogeneous in itself, but, as it represents an average of a variety of uniform constituent parts, all the charges of the converter from time to time will be substantially uniform, and the products of all will be homogeneous. To this end my invention may be practiced with a variety of forms of apparatus—for example, by merely receiving in a charging-ladle a number of small portions of metal taken from several ladles or receiving vessels containing crude metal obtained at different times or from different furnaces, the mixing being performed merely by the act of pouring into the charging-ladle, and other like means may be employed. I prefer, however, to employ the apparatus shown in the accompanying drawings, and have made it the subject of a separate patent application, Serial No. 220,672, and, without intending to limit the invention to the use of that specific apparatus, I shall describe it particularly, so that others skilled in the art may intelligently employ the same.

originally presented and amended the two claims embodied in the patent as finally issued, and which have been previously set out.

It plainly results from the amendment that it was drawn to meet the objection of the Examiner and to make clear the fact that the character of the mixing contemplated by the Jones process was not that resulting from a continuous operation of a reservoir by the inflowing and outdrawing of metal with a constant retention of a residuum, but was a distinct character of mixing by thorough commingling of batches of metal, in order to produce in a reservoir a molten metal which would be homogeneous and uniform, of a character deemed to be unattainable by the continuous process; the purpose of securing this reservoir of uniform metal being to obtain a mixed metal so uniform in its chemical constituents that it might be, with greater advantage than theretofore, subjected to further treatment in the converters or be run into pigs, which, by reason of the uniform quality of the metal, might then be used for any purpose where such a metal was desired. In other words, the amendment was drawn for the purpose of satisfying the Patent Office that the method which was claimed should not be rejected, because the prior art provided against mere variations in the metal drawn from the reservoir, as the patent went further and described a process of mixing which would bring about the greater result of a uniform molten metal and consequent uniform product.

This conclusion is rendered clear by the fact that the amended application not only retained in substance all the prior declarations as to the purpose of obtaining a uniform mixed molten metal, and as to the use of such uniform metal, in converters or otherwise, but emphasized the same by adding the following:

To this end my invention may be practiced with a variety of forms of apparatus. For example, by merely receiving in a charging-ladle a number of small portions of metal taken from several ladles or receiving vessels containing crude metal obtained at different times or from different furnaces, the mixing being performed merely by the act of pouring into the charging-ladle, and other like means may be employed.

And to make the object of the amendment perfectly clear, the prior description of the method was supplemented by stating that the—

commingling of the contents may be aided by agitation of the vessel on its trunnions, so as to cause the stirring or shaking of its liquid contents.

True it is that on the trial below the complainant presented a disclaimer, which the Court now upholds, by which he sought to eliminate from the patent the amendments which had been inserted to meet the objections of the Patent Office Examiner, and which indubitably fixes the meaning of the patent. I do not deem it necessary, however, to stop to refer to authorities to show that a disclaimer which, in effect, has for its object the making of a new patent by striking out the essential representations upon which the patent was granted, is without legal warrant. This, it is submitted, is the obvious result of the antithesis to which the opinion of the Court refers.

But even if the patent as it is now made over, as I think, by the effect which is given by the Court

to the disclaimer, be alone considered, it plainly results that the patent as so changed did not contemplate, as now decided, solely the prevention of abrupt variations in the metal drawn from the reservoir for use in the converter, since the patent yet provides:

Instead of discharging the metal into the cars it and carrying it in the cars to the converters or casting-house, the vessel 1 may be an adjunct relative to the other parts of a furnace plant so to deliver its contents immediately to the converters or other place where it is to be utilized.

I fail to see how it can be held, even giving the fullest effect to the disclaimer, that the patent provides only for metal to be supplied to a converter, when it expressly points out that the metal may be used "in the casting-house, in the converters or other place where it is to be utilized."

I come now to the statements found in the patent to which I have previously alluded, which the Court thinks give support to the claim that the patent had reference merely to the avoidance of abrupt variations in metal supplied to the converters. The statements thus relied upon are contained in that portion of the patent where the mode of operation of the appliance covered by the apparatus patent is described. These passages are excerpted in the margin.*

*Referring now to the drawings, 2 represents the reservoir before mentioned. It consists of a covered hollow vessel having an outer casing, 2, of iron or steel, which is suitably braced and strengthened by interior beams and tie-rods, as shown in the drawings. The whole exterior of the vessel is lined with fire-brick or other refractory lining, which should be of sufficient thickness to retain the heat of the molten contents of the vessel and to prevent chilling thereof. The vessel is strongly braced and supported by braces and tie-rods, and may be of any convenient size, holding, say, one hundred tons of metal, (more or less,) and its shape is preferably such as shown in the drawings, being rectangular, or nearly so, in cross-section and an irregular trapezium in longitudinal section, one end being considerably deeper than the other. At the top of the deeper end, which I call the "rear" end, is a hopper, 3, into which the molten metal employed in charging the vessel is poured, and at the front end is a discharge-spout, 4, which is so located that the bottom of the spout is some distance above the bottom of the vessel—say two feet in a hundred-ton tank, and more or less, according to the capacity of the vessel—the purpose of which is that when the metal is poured out of the spout a considerable quantity may always be left remaining and unpoored, and that whenever the vessel is replenished there may already be contained in it a body of molten metal with which the fresh addition may mix. Thus secured, as much as possible, uniformity in character of the metal which is fed to and discharged from the tank, and cause the fluctuations in quality of the successive loadings to be very gradual.

The mode of operation of the apparatus is as follows: When the vessel is in the backwardly-inclined position shown in Fig. 1, it is ready to receive a charge of metal from the cars 5. Before introducing the first charge, however, the mixing vessel should be heated by internal combustion of coke or gas, and when the walls of the vessel are sufficiently hot to hold the molten metal without chilling it it is charged repeatedly from the cars 5 with metal obtained either from a number of furnaces or at different times from a single furnace. The charges of metal introduced at different times into the vessel, though differing in quality, mix together, and when the vessel has received a sufficient charge its contents constitute a homogeneous molten mass, whose quality may not be precisely the same as that of any one of its constituent charges, but represents the average quality of all the charges. If desired, the commingling of the contents may be aided by agitation of the vessel on its trunnions, so as to cause the stirring or shaking of its liquid contents. The mixing chamber being deeper at its rear than at the front end, as before described, and its normal position when not discharging metal for the purpose of casting being with the bottom inclined upward toward the front or discharging end, and the bottom of the spout being situated above the bottom of the vessel at its forward end, it is adapted to receive and hold a large quantity of molten metal without its surface rising high enough to enter the discharge-spout.

After the vessel is properly charged, the metal is drawn off into the cars 6 from time to time, as it is needed, by opening the door or cover 15 of the spout 4 and driving the engine 11, so as to elevate the rear end of the vessel and tilt it forward, and thus to discharge any required amount of its contents in the manner before explained into the cars 6, which are transported to the converters, or the metal is cast into pigs or otherwise used. The tilting of the vessel does not, however, drain off all the contents thereof, a portion being prevented from emptying by reason of

When the passages in question are properly considered, it becomes, I submit, incontrovertible that, instead of sustaining, they are antagonistic to the construction which has been given by the Court to the patent, and hence sustain the construction which has been presented in this dissent.

Referring to the excerpted matter in the margin, it will be seen that in the second paragraph is described the mode of filling the reservoir. Various portions of metal, termed "charges," are drawn "either from a number of furnaces or at different times from a single furnace," and such charges are introduced into the reservoir until the vessel is full, that is, to use the language of the patent, until a "sufficient charge" has been supplied to the reservoir, the result being, as stated in the patent, that the charges of metal thus accumulated in the reservoir "constitute a homogeneous molten mass, whose quality may not be precisely the same as that of any one of its constituent charges, but represents the average quality of all of the charges." Thus it appears that the patentee had in mind the cure of the inequalities or variations present in the "charges" of metal poured into the reservoir to make up the "sufficient charge," and thereby to cause such sufficient charge "to constitute a homogeneous molten mass, whose quality may not be precisely the same as that of any one of its constituent charges, but represents the average quality of all the charges." And the production of this homogeneous mass, it is further observed, "may be aided by the agitation of the vessel on its trunnions, so as to cause the stirring or shaking of its liquid contents." Manifestly, not only the obtaining of the homogeneous molten mass is absolutely incompatible with the theory that the patent related to mere variations, but the statement about the agitation of the vessel on its trunnions is likewise a negation that the conception of the patent related to the continuous inflowing and outflowing of molten metal from the reservoir. The construction now put upon the patent by the Court disregards the provision that the variation which was to be cured was that existing between the "charges" as they were poured in, and assumes—contrary to the language of the patent—that the purpose was to cure variations which would exist in the mass of molten metal, when, by a sufficient charge, the reservoir had been filled. And this, although it is expressly declared in the patent that by the operation of the reservoir, in the mode described, the variations existing in the metal before the pouring in would be destroyed by the mixing, which would cause the mass from which withdrawals were to be made to become homogeneous.

The error becomes more manifest upon an examination of the last of the excerpted paragraphs, wherein is contained directions as to the with-

drawals of the equalized metal from the sufficient charge, that is, the filled reservoir of equalized metal and the replenishing of the reservoir with new charges to make another sufficient charge. It will be seen that the patent contemplated the discharge of the mass of homogeneous metal by tilting the tank down to a residue, and that no reference is made to replenishing the reservoir until provision is made for the retention of a residue. Then the reservoir is to be replenished by the addition of new charges which mix with these parts of previous charges, which have been equalized and which remain in the reservoir as a residue. Obviously, in this subsequent addition of charges it was intended that a "sufficient charge" of metal should be contained in the reservoir, which, when thoroughly mixed, would form another homogeneous mass of molten metal, it being declared "by which means any sudden variations in the quality of the metal supplied to the converter is avoided." "By which means" is clearly meant the bringing into existence of the homogeneous mass referred to in the patent. In other words, the patent points out that by making all the "constituent charges" of a "sufficient charge" homogeneous there would be no variations in the withdrawals from that equalized mass. And this is besides made more manifest by the following sentence in which attention is called to the fact that the equalized metal thus drawn off might be carried to the converters or be cast into pigs without treatment in the converters.

Moreover, turning to the first paragraph in the excerpt, it will be perceived that it is stated that the operation of the mixer as described will—

secure, as much as possible, uniformity in the character of the metal which is fed to and discharged from the tank, [meaning the equalized mass.] and cause the fluctuations in the quality of the molten metal to be very gradual.

That is to say, the patent contemplated that each distinct full reservoir or sufficient charge, constituting a batch of metal, would be homogeneous in itself and substantially uniform in its chemical constituents, and the successive "sufficient charges" or "full reservoirs" would, by means of the residuum, vary but slightly between each other. The words "successive tappings" can have no other meaning than successive batches, for it is impossible to conceive that they could refer to the separate withdrawals of metal taken from one full reservoir or sufficient charge, because it had been declared that the "constituent charges" of each full reservoir of metal by the operation described would become homogeneous; that is, practically uniform.

Certainly, this construction of the patent gives effect to all of its provisions, and harmonizes with its plain letter, while the contrary construction, now approved by the Court, reads out of the patent the repeated statements as to the purpose of the patent being to secure a uniform molten metal and disregards the fact that the patent expressly provides that what it aims to secure is such uniform metal as is fit not only for use in converters but for castings and any other mode by which such

[Vol. 39, No. 8.]

a metal can be utilized. Certainly, what has been previously stated is a demonstration that the construction previously given by me accords with the express declaration made by the patentee when he applied for his patent, and is strictly in harmony with the action of the Patent Office in allowing the patent. It is equally clear that the construction of the patent, which has been by me elucidated, is besides in accord with the conception entertained by the Patent Office of the meaning of the patent long after it had been issued. Thus, the Commissioner of Patents, in a report bearing date January 1, 1898, reviewing the advance in the industrial arts, said, (Italics mine):

A process now commonly used in steel manufacture is that of Patent No. 404,114, January 4, 1889, to Jones, in which he described a means of getting a uniform product of metal by mixing together in a suitable receptacle, batches of metal from different furnaces, so that the mixture when drawn off will be the average of the different charges.

As the views hereinbefore expressed sufficiently make manifest the reasons for my dissent, it is unnecessary to stop to notice many matters considered in the opinion of the Court. Lest, however, if they are not referred to, it may be assumed that assent is given to them, the more important of such statements are briefly adverted to. First, it is said that the making of steel by the direct process was commercially impracticable before the grant of the Jones patent, and that that patent operated a revolution in the art. The proposition, in my opinion, finds no support in the record. On the contrary, it is affirmatively established that not only on the Continent but in England and in this country, long prior to the grant of the Jones patent, Bessemer steel was made by the direct process, upon a large scale, continuously and successfully. So far as revolution in the art is concerned by the alleged enormous saving rendered possible by the use of the Jones method, it is not perceived how such a statement is compatible with the unquestioned proof in the record that, although the complainants at their Edgar Thompson works erected several of the Jones mixers about the time of the grant of the Jones patent, they did not introduce them into their other works until more than seven years afterward. Indeed, to my mind it is established by the record that the Jones method, when put into practical operation by the

[Vol. 39, No. 8.]

complainant, proved not to be a commercial success, and the apparatus was continued in use despite this fact because of the means which it afforded of securing on a larger scale the benefits of storage hitherto well known in practice, and that the use of this larger storage vessel became more and more advantageous as the capacity of blast-furnaces was enlarged and improvements took place in the mode of their operation.

The statement that upon the grant of the Jones patent the so-called mixer was at once adopted by steel-works generally in this country is also unwarranted by the facts in evidence, which establish without any conflict that storage-reservoirs of like capacity to that of the Jones apparatus were in use at the time of the hearing of this cause in but three steel-works in the United States outside of those operated by the complainant, and that their introduction long after the grant of the Jones patent in such outside works is shown to have been coincident with the increase in blast-furnace output and the necessity which had thus arisen for greater reservoir capacity to hold the enormous supply of molten metal which was then being produced by the operation of blast-furnaces. The record, moreover, establishes that in the works in question, where long after the grant of the Jones patent large reservoirs were first employed, this was done not because better results were secured by means of mixing than had been obtained by the mixing theretofore resorted to, but because the larger output of blast-furnaces pointed to the necessity for the construction of a larger reservoir than those previously employed.

The effect of the decision now rendered it seems to me is, therefore, to put the patentee in a position where, without invention on his part, and without the possession by him of lawful Letters Patent, he is allowed to exact tribute from the steel and iron making industry, whenever those engaged in such industry desire to increase their plants or to more conveniently and satisfactorily conduct their operations so as to keep pace with the natural evolution of modern industrial development.

I am authorized to say that the CHIEF JUSTICE, Mr. Justice HARLAN and Mr. Justice BREWER concur in this dissent.

Design Patents.

AN ACT to amend section forty-nine hundred and twenty-nine of the Revised Statutes, relating to design patents.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That section forty-nine hundred and twenty-nine of the Revised Statutes be, and the same is hereby, amended so as to read as follows:

Sec. 4929. Any person who has invented any new, original, and ornamental design for an article of manufacture, not known or used by others in this country before his invention thereof, and not patented or described in any printed publication in this or any foreign country before his invention thereof, or more than two years prior to his application, and not in public use or on sale in this country for more than two years prior to his application, unless the same is proved to have been abandoned, may, upon payment of the fees required by law and other due proceedings had, the same as in cases of inventions or discoveries covered by section forty-eight hundred and eighty-six, obtain a patent therefor.

Approved May 8, 1902.

Hearings.

DEPARTMENT OF THE INTERIOR,

UNITED STATES PATENT OFFICE,

Washington, D. C., May 15, 1902.

Notice is hereby given that there will be no cases placed upon the docket to be heard by either the Commissioner or the Assistant Commissioner during the months of July and August 1902.

V. L. ALLEN,
Commissioner.

APPLICATIONS UNDER EXAMINATION.

Condition at Close of Business May 30, 1902.

Room No.	Divisions and subjects of invention.	Oldest new application and oldest action by applicant awaiting office action.		No. of applications awaiting action.
		New.	Amended.	
In arrears—Under one month.				
217	XXXIII. "DESIGNS," TRADE-MARKS, LABELS AND PRINTS, Options, and Photographs.	May 6	May 10	64
140	III. Metallurgy, Metal-Founding, Electro-Chemistry, Coating with Metal, etc.	May 1	May 8	176
106	II. Farm Stock, Products, etc., Lubricators, Presses, Stationery, etc.	May 1	May 7	268

Revision of Trade-Mark Rules.

(ORDER NO. 1,461.)

DEPARTMENT OF THE INTERIOR.

UNITED STATES PATENT OFFICE.

Washington, D. C., April 2, 1902.

Rule 21, subdivision (3), governing the registration of trade marks, is hereby amended to read as follows:

(b) A statement specifying name, domicile, location, and citizenship of the party applying; the class of merchandise and the particular description of goods comprised in such class to which the particular trade-mark has been appropriated; a description of the trade-mark itself, and a statement of the mode in which the same is applied and affixed to goods, and the length of time during which the trade-mark has been used, and if the applicant be a corporation it must set forth under the laws of what State or nation incorporated.

F. L. ALLEN,
Commissioner.

Index.

(ORDER NO. 17.)

All applications, communications, and other instruments in writing or print, which should properly constitute a permanent record in this Office, must be prepared with a substantially permanent ink. Aids and other perishable aids will not be accepted.

PATENTS

GRANTED MAY 27, 1902.

700,719. WATER-GLASS RECEPTACLE FOR RAILWAY CARS.
PATRICK A. ALLEN and JOHN W. McKINNEY, Toledo, Ohio. Filed Jan. 14, 1898. Serial No. 92,073. (No model.)

Claim.—1. In a water-cistern of the class described, the combination, with a bowl and a chute arranged beneath said bowl in such manner as to receive deposits directly therefrom and expel them through an opening provided for that purpose, of a tank attached to the side of said chute and independent thereof, an opening provided between said chute and tank, a gate in said opening and adapted when open to close passage in chute and cause deposits to enter said tank, substantially as described.

2. In a water-cistern, the combination of a bowl, a chute arranged directly beneath said bowl, a tank arranged at the side of said chute, the said chute adapted to be used independently of said tank and to expel contents directly therefrom without first entering tank, inlet and outlet openings provided in said tank, gates in said openings, the gate in said inlet-opening being adapted, when in open position, to close passage in chute and cause deposits to enter said tank, and means for opening and closing said gates.

3. In a water-cistern adapted to be used on railway-cars, the combination, with a bowl and a chute directly connected to said bowl and having two outlet-openings, of a tank arranged at the side of said chute and having an inlet and outlet opening, said inlet-opening communicating with one of said outlet-openings in said chute, a valve in each of said openings in tank and each adapted to alternately open outwardly, the said valve in the inlet-opening of said tank being adapted when open to close passage in chute and cause deposits to enter tank, and means, comprising equal-arms on said valves, a rod connecting said arms and a lever attached to and adapted to manipulate said rod, provided to operate said valves.

4. In a water-cistern, the combination of a bowl, a straightway chute contiguous to said bowl and having a direct outlet-passage, a tank, having inlet and outlet openings, attached to the side of said chute and adapted to be used only when it is desired to retain the contents, gates in said openings, one of said gates adapted to swing outwardly and downwardly and close the passage in said chute in such manner as to cause contents to change their course, when being expelled through, and enter said

tank, and means provided for causing the gate in said outlet-passage to open outwardly and upwardly, substantially as described.

5. In a water-cistern of the class described, the combination with a bowl and straightway chute, of a tank having a circular and forwardly-inclined floor, said tank being provided with a passage communicating with said chute and an outlet-passage, valves adapted to alternately open and close said passages, the valve in said inlet-passage adapted to open outwardly and downwardly and close passage in said chute and means for operating said valves, said means comprising arms attached to said valves, a rod connecting said arms, and a lever pivoted to floor of car and connected with said rod, substantially as specified.

6. In a water-cistern of the class described, the combination with a bowl, a straightway chute projecting downwardly therefrom and having an opening in its side, of a retaining-reservoir having inlet and outlet passages, said inlet-passage communicating with opening in side of said chute, a forwardly-inclined floor in said tank, a shaft mounted at the forward end of said floor, a valve on said shaft and adapted to close the chute when in open position and cause deposits to enter said reservoir through the said inlet-passage, a shaft on the rear of said tank, a stem secured to said shaft, a valve on said stem and adapted to swing in the outlet-opening in said tank, and means for alternately opening and closing said valve, substantially as specified.

7. In a water-cistern, the combination of a bowl, a straightway chute connected directly with said bowl and having a direct and indirect discharge-opening, a tank contiguous to said bowl and having an inlet and outlet opening, through said opening, with bowl, an independent outlet-opening provided in said tank, valves mounted in the openings in said tank, one of said valves being adapted to open outwardly and upwardly and the other to open outwardly and downwardly and close direct discharge-opening in chute, and means provided for operating said valves.

8. In a water-cistern, the combination, with a bowl, of a receptacle having a direct outlet-opening in a vertical line with said bowl and a second outlet-opening at an angle to said bowl, valves mounted adjacent to said openings, the said valves being adapted to simultaneously close said openings and retain matter in said receptacle.

9. In a water-cistern, the combination, with a bowl, of a receptacle contiguous to said bowl and having two compartments, one of said compartments being in a vertical line with said bowl and adapted to receive matter directly therefrom and having a direct outlet-opening, the other compartment having a downwardly and outwardly declined floor and an outlet-opening at its lower extremity, a valve interposed between the said compartments and adapted when open to close outlet in the said vertical compartment and cause the matter received from said bowl to enter the said other compartment and be retained therein by means of a valve mounted in the said opening at its lower extremity, and means for opening and closing said valve, substantially as described.

700,720. IMPROVED LAMP. WILLIAM E. ARNOLD, Watsonville, Cal. Filed May 2, 1891. Serial No. 81,821. (No model.)

Claim.—1. A lamp of the character described with top, bottom and three sides fixed together, the door hinged thereto, an lamp located near the top with a short side in front, three sides extending higher up, a center opening through bottom of lamp, a rim surrounding center opening, a cap placed above center opening, a movable front attached to sides of lamp in such a way as to be raised up to open the front, a drain-tube attached to the bottom of lamp, a covering of wood or other suitable material, a trap and discharge-pipe connecting therewith, a flexible tube extending through the cover, substantially as described.

2. A refrigerator-car having sides, top, bottom, and door, an lamp and drain-tube, sides at the sides having portions of their length removed for the free circulation of air, central upright pipes, sides at

ceded to said central piece spaced from each other to permit circulation of air and trays sliding on said slides, substantially as described.

3. A refrigerator-case having sides, top, bottom and door, an ice-pan and drainage-tube, slides supported at the sides and spaced therefrom to permit free circulation of air, central upright piece, slides on said central piece spaced therefrom with the like object, and trays sliding on said slides, substantially as described.

4. A refrigerator-case comprising an ice-pan located near the top with a short side in front and three sides of greater height, a movable front attached to the sides of the ice-pan so that it can be raised to open the front, a central opening through the bottom of the ice-pan, a drainage-tube therefrom, and a trap and discharge-pipe connected therewith, substantially as described.

5. A refrigerator-case comprising an ice-pan, slides, trays on said slides, grooved upright side pieces near the door of the case, and strips of suitable flexible material corresponding in height to the height between the slides, the ends of said strips being inserted in said grooves, and movable thereby by flexing or springing the strips from said grooves whereby the strips may be removed from the grooves without sliding the same up or down, substantially as described.

700,721. REFRIGERATOR-CASE. WILLIAM E. ANNE, WILSON, Cal. Filed July 4, 1901. Serial No. 67,505. (No model.)

Claim.—1. In a refrigerator-case, the combination with upright supports having a plurality of series of sockets, the sockets of one series being spaced at different intervals from those of another series, of hangers having one end removably inserted in said sockets, rails through which the other ends of the hangers pass to support the same, and trays sliding on said rails, substantially as described.

2. In a refrigerator-case, the combination of supports having downwardly-inclined sockets, wire hangers having downwardly-bent portions in said sockets, rails in which the other ends of said hangers are inserted, and trays sliding on said rails, substantially as described.

3. In a refrigerator-case, the combination of trays, vertical supports therefor, guides in which said supports slide, and springs for resiliently sustaining said supports, substantially as described.

700,722. PAPER-BAG-DELIVERY DEVICE. DANIEL APPEL, Cincinnati, Ohio, assignor to the Union Paper Bag Machine Company, Philadelphia, Pa. Filed Jan. 12, 1902. Serial No. 69,099. (No model.)

Claim.—1. The combination, substantially as set forth, of a first pair of cooperating rolls adapted to advance and discharge a succession of paper bags and foremost, a second pair of rolls disposed to one side of the normal path of the bags discharged by the first rolls, and a movable switch disposed between said two pairs of rolls and adapted in one position to be out of the normal path of the bags discharged by the first rolls and in another position to be in that path and deflect the bags out of the normal path and into the bite of the second rolls.

2. The combination, substantially as set forth, of a first pair of cooperating rolls adapted to advance and discharge a succession of paper bags and foremost, a second pair of rolls disposed to one side of the normal path of the bags discharged by the first rolls, a movable switch disposed between said two pairs of rolls and adapted in one position to be out of the normal path of the bags discharged by the first rolls and in another position to be in that path and deflect the bags out of the normal path

and into the bite of the second rolls, and mechanism for automatically shifting said switch from one to the other of its positions.

3. The combination, substantially as set forth, of a first pair of cooperating rolls adapted to advance and discharge a succession of paper bags and foremost, a second pair of rolls disposed to one side of the normal path of the bags discharged by the first rolls, a movable switch disposed between said two pairs of rolls and adapted in one position to be out of the normal path of the bags discharged by the first rolls and in another position to be in that path and deflect the bags out of the normal path and into the bite of the second rolls, and a surface adapted to receive the bags from the second pair of rolls and having a discharging declination toward the normal path of bags discharged by the first pair of rolls.

4. The combination, substantially as set forth, of a first pair of cooperating rolls adapted to advance and discharge a succession of paper bags and foremost, a second pair of rolls disposed to one side of the normal path of the bags discharged by the first rolls, a movable switch disposed between said two pairs of rolls and adapted in one position to be out of the normal path of the bags discharged by the first rolls and in another position to be in that path and deflect the bags out of the normal path and into the bite of the second rolls, and a fifth roll cooperating with a roll and adapted to discharge bags toward the normal path of discharge from the first pair of rolls, and means for receiving bags from the second pair of rolls and delivering them opposite and forward to the action of the fifth roll.

5. The combination, substantially as set forth, of a first pair of cooperating rolls adapted to advance and discharge a succession of paper bags and foremost, a second pair of rolls disposed to one side of the normal path of the bags discharged by the first rolls, a movable switch disposed between said two pairs of rolls and adapted in one position to be out of the normal path of the bags discharged by the first rolls and in another position to be in that path and deflect the bags out of the normal path and into the bite of the second rolls, and a fifth roll cooperating with a roll and adapted to discharge bags toward the normal path of discharge from the first pair of rolls, and a surface adapted to receive bags from the second pair of rolls and having a discharging declination to the bite of the fifth roll.

6. The combination, substantially as set forth, of a first pair of cooperating rolls adapted to advance and discharge a succession of paper bags and foremost, a second pair of rolls disposed to one side of the normal path of the bags discharged by the first rolls, a movable switch disposed between said two pairs of rolls and adapted in one position to be out of the normal path of the bags discharged by the first rolls and in another position to be in that path and deflect the bags out of the normal path and into the bite of the second rolls, and a fifth roll cooperating with one of the rolls of the second pair and adapted to discharge bags toward the normal path of discharge of the first pair of rolls, and means for receiving bags from the second pair of rolls and delivering them opposite and forward by the action of the fifth roll.

7. The combination, substantially as set forth, of a first pair of co-

operating rolls adapted to advance and discharge a succession of paper bags and foremost, a second pair of rolls disposed to one side of the normal path of the bags discharged by the first rolls, a movable switch disposed between said two pairs of rolls and adapted in one position to be out of the normal path of the bags discharged by the first rolls and in another position to be in that path and deflect the bags out of the normal path and into the bite of the second rolls, and a fifth roll cooperating with one of the rolls of the second pair and adapted to discharge bags toward the normal path of discharge of the first pair of rolls, and a surface adapted to receive bags from the second pair of rolls and having a discharging declination to the bite of the fifth roll.

8. The combination, substantially as set forth, of a first pair of cooperating rolls adapted to advance and discharge a succession of paper bags and foremost, a traveling apron having its inner surface engaging one of said rolls and its outer surface engaging the other of said rolls, a second pair of rolls disposed to one side of the normal path of the bags discharged by the first rolls, and a movable switch disposed between said two pairs of rolls and adapted in one position to be out of the normal path of the bags discharged by the first rolls and in another position to be in that path and deflect the bags out of the normal path and into the bite of the second rolls.

9. The combination, substantially as set forth, of roll mechanism adapted to advance and discharge a succession of paper bags in a downward direction and foremost, an endless receiving-apron disposed below said roll mechanism and having a declination transverse to its line of travel and adapted to receive the bags coming from the roll mechanism, and an upwardly-projecting wall extending along the lower edge of said receiving-apron and adapted to be engaged by the foremost ends of the bags and to maintain the bags upon the apron.

10. The combination, substantially as set forth, of roll mechanism adapted to advance and discharge a succession of paper bags and foremost, an endless horizontal receiving-apron adapted to receive the bags and having a downward curve at the portion where the bags are to be discharged, and an endless retaining-apron running contiguous to the downwardly-disposed portion of the receiving-apron and adapted to hold the descending bags to the receiving-apron.

11. The combination, substantially as set forth, of roll mechanism adapted to advance and discharge a succession of paper bags and foremost, an endless horizontal receiving-apron adapted to receive the bags and having a downward curve at the portion where the bags are to be discharged, an endless retaining-apron running contiguous to the downwardly-disposed portion of the receiving-apron and adapted to hold the descending bags to the receiving-apron, the retaining-apron and the cooperating portion of the receiving-apron having a quarter-twist, and a receiving-box at the discharge-point of the two aprons.

12. The combination, substantially as set forth, of roll mechanism adapted to advance and discharge a succession of paper bags and foremost, carrying-rolls for endless aprons, a receiving-apron adapted to receive the paper bags from the roll mechanism as an overlapping series of bags disposed transversely on the apron, a receiving-box disposed at the discharge-point of said receiving-apron and having an end wall substantially tangent to the tail roll of the apron at the point of bag discharge therefrom, and a retaining-apron cooperating with the discharge portion of the receiving-apron.

13. The combination, substantially as set forth, of a first pair of cooperating rolls adapted to advance and discharge a succession of paper bags and foremost, a second pair of rolls disposed to one side of the normal path of the bags discharged by the first rolls, a movable switch disposed between said two pairs of rolls and adapted in one position to be out of the normal path of the bags discharged by the first rolls and in another position to be in that path and deflect the bags out of the normal path and into the bite of the second rolls, and a receiving-apron adapted to receive the bags in succession as they come either from the second pair of rolls or direct from the first pair of rolls.

14. The combination, substantially as set forth, of a first pair of cooperating rolls adapted to advance and discharge a succession of paper bags and foremost, a second pair of rolls disposed to one side of the normal path of the bags discharged by the first rolls, a movable switch disposed between said two pairs of rolls and adapted in one position to be out of the normal path of the bags discharged by the first rolls and in another position to be in that path and deflect the bags out of the normal path and into the bite of the second rolls, a receiving-apron adapted to receive the bags in succession as they come either from the second pair of rolls or direct from the first pair of rolls, and mechanism for automatically moving said switch.

15. The combination, substantially as set forth, of an inclined receiving-box adapted to receive a pile of paper bags, a lower end wall for said box adapted to support the pile of bags, and roller and apron mechanism adapted to advance a succession of bags and foremost and then side edge foremost and deliver them side edge foremost upon said end wall under the pile of bags in said box.

700,723. HAY-LOADING APPARATUS. THOMAS F. BERRILL, Port Wayne, Ind. Filed Mar. 17, 1902. Serial No. 68,541. (No model.)

Claim.—1. In a hay-loading apparatus a hay wagon or truck; a gear-wheel fixed upon one of the rear wheels of said truck; a pair of rotatable shafts in transverse arrangement carrying upon one end thereof gear-wheels in co-operative arrangement with the said gear, as described; winding-drums fixed on said shafts respectively; a traveling bar suspended above said wagon by means of draft-cables; two pairs of draft-cables having their upper ends secured to said bar and extending in opposite directions over suitable guides to the said drums respectively, to which their other end is secured and upon which they are adapted to be wound; and means for shifting the said drum-shaft gears into engagement with the said actuating-gear for the purpose described.

2. In combination with a hay-wagon, a hay-loading apparatus consisting of a driving-gear fixed upon one rear wheel of the said wagon as shown; rotatable transverse shafts carrying upon one end thereof gear-wheels adapted to be thrown, one at a time, into engagement with the said gear, as described; winding-drums fixed on said shafts respectively; a traveling leader-bar suspended above the wagon by the draft-cables; draft-cables having one end secured to said drums and the other end secured to the said traveling bar, and adapted to move the same to and fro above the said wagon under the impulse of the said gears; means for normally securing said gears out of engagement; and means for holding said gear-wheels into engagement with the said actuating-gear.

3. A hay wagon or truck carrying upon one of its rear wheels a fixed driving gear-wheel; transverse drums adjustably mounted in laterally-adjustable bearings and carrying upon one end thereof a fixed gear-wheel adapted to be shifted into mesh with said driving-gear; means for normally holding said wheels out of such engagement; means for shifting the said wheels into an actuating engagement with the said gear; a traveling leader-bar provided with a series of lines for grasping and moving the hay as described, and suspended above the wagon by means of forward and rear draft-cables; and draft-cables having one end secured to the said drums respectively, and having the other end secured to the said bar as described, and adapted to actuate the bar.

4. In a hay-loading apparatus a pair of rotatable drums in parallel arrangement carrying upon one end thereof a gear-wheel; a driving-gear adapted for an actuating engagement with the said wheels as described; means for normally securing said wheels out of such engagement; means for causing said wheels when desired, to be in actuating engagement with the said gear; a traveling leader-bar suspended by forward and rear actuating draft-cables; and draft-cables having one end secured to said bar and the other end secured to said drums upon which they are adapted to be wound.

700,724. SWAGE-MACHINE. BENJAMIN F. BLISS, Pawtucket, R.I.; John S. Bliss, assignors of said Benjamin F. Bliss, deceased. Filed Apr. 3, 1902. Renewed Mar. 20, 1902. Serial No. 69,572. (No model.)

Claim.—The herein-described swage-block having its edges and sides provided with a plurality of forming-rollers; a journal 2 formed on each end of said block; a series of radiating grooves 20 formed on each end of the block adjacent to said journals, in combination with supporting end sections 4 having bearings 5 in the upper ends thereof; flanges 9 located adjacent to said bearings and adapted to cooperate with the radial grooves 20, and a clamping-rod 7 and means to rotate said rod whereby the sections 4 may be drawn tightly into engagement with the ends of the swage-block or released, as desired, substantially as specified and for the purpose set forth.

700,725. FOOD-CUTTER. JOHN A. DEAN, Mayger, Oreg. Filed May 20, 1901. Serial No. 66,211. (No model.)

Claim.—In a combined chopper and cutter, the combination with the blade A, formed with the arched brace A', and the tubular extension A'; of the inner knife C, concentric with the said knife A, formed with the bifurcated brace C', and spindle C, indented with pin c, and arranged to engage, and pass through the hollow of the cylindrical extension A'; a handle B, upon the upper end of said cylindrical extension; and the set-screw D, threaded in said cylindrical extension A', and engaging the pin c, in said spindle C, all substantially as and for the purpose set forth.

700,726. PIANO ATTACHMENT. GARSON L. C. BAKER, Duluth, Minn., assignor of one-half to Hugh F. Allen, Duluth, Minn. Filed Apr. 22, 1901. Serial No. 67,008. (No model.)

Claim.—1. The combination with a piano, of a series of independent sound-controlling and intensifying devices arranged in juxtaposition to the sound-

ing-board thereof, and having at their ends means for securing the same in position, sound-transmitting strips interposed between the said sound-controlling-board and said sound-containers, and means for adjusting each of said sound-containers independently of the others.

2. The combination with a piano, of a series of independent sound-containers and intensifiers arranged in juxtaposition to the sounding-board thereof, each of said sound-containers and intensifiers being of semicircular cross-sectional contour, and having at their ends means for securing the same in position, sound-transmitting strips interposed between the said sound-controlling-board and said sound-containers, and means for adjusting each of said sound-containers independently of the others.

3. The combination with a piano having a series of brackets secured to the back thereof, of a series of independent sound-containers and intensifiers arranged in juxtaposition to the sounding-board thereof, each of said sound-containers and intensifiers being of semicircular cross-sectional contour, and having at one end means for securing the same in position and having at their opposite ends curved-threaded cheeks adapted to pass through the said brackets, sound-transmitting strips interposed between the said sound-controlling-board and said sound-containers, and nuts on the ends of the said curved-threaded cheeks whereby each of said sound-containers can be adjusted independently of the others.

700,727. APPARATUS FOR TREATING GARBAGE. EDWIN B. BUCHHEIT, Syracuse, N. Y. Filed Sept. 2, 1901. Serial No. 74,748. (No model.)

Claim.—1. In combination with the supporting-roller, a series of separate and independently-movable compressing-rollers disposed contiguously side by side, and guards disposed to engage the front and rear peripheral faces of the compressing-rollers to maintain said rollers in operative position over the supporting-roller as set forth.

2. In combination with the supporting-roller, a series of separate and independently-movable compressing-rollers disposed contiguously side by side, and a corresponding series of separate and independently-movable guard-rollers disposed to engage the peripheries of the compressing-rollers and maintain said rollers in operative position on the supporting-roller as set forth.

3. In combination with the supporting-roller, a series of separate and independently-movable compressing-rollers disposed contiguously side by side, shafts disposed in front and rear of said compressing-rollers and parallel with the axis of the supporting-roller, and a plurality of guard-rollers mounted revolvably independent of each other on said shafts and arranged in series corresponding to the series of compressing-rollers and in range therewith as set forth.

4. The combination with the longitudinally-traveling conveyor provided with ducts for discharging the compressed material and a plurality of rollers supporting said conveyor at intervals of its length, of compressing-rollers riding by gravity upon the conveyor, and guards disposed to

engage the front and rear faces of the compressing-rollers and maintain said rollers in operative position over the supporting-roller as set forth.

5. The combination with the longitudinally-traveling conveyor provided with discharging-ducts, and a plurality of rollers supporting said conveyor at intervals of its length, of a corresponding plurality of series of compressing-rollers riding by gravity upon the conveyor, the rollers of each series being disposed contiguously side by side and revolvable independent of each other, shafts disposed between the successive series of compressing-rollers and parallel with the supporting-roller, and a corresponding series of separate and independently-revolvable guard-rollers mounted on each of said shafts as set forth.

6. The combination with the longitudinally-traveling conveyor provided with discharging-ducts and a plurality of rollers supporting said conveyor at intervals of its length, of a corresponding plurality of series of separate and independently-revolvable compressing-rollers riding by gravity upon the conveyor, the rollers of each series being disposed contiguously side by side and with their tracks in lines intermediate the tracks of the adjacent series, shafts extending between the successive series of compressing-rollers and parallel with the supporting-roller, and guard-rollers mounted on said shafts and revolvable independently of each other as set forth.

700,728. BINOCULAR STETHOSCOPE. ROBERT G. H. BOWLER, Boston, Mass. Filed Mar. 5, 1901. Serial No. 64,804. (No model.)

Claim.—1. A binocular stethoscope comprising a diaphragm-receiver adapted to be applied to the patient to be examined, ear-tubes communicating with said receiver, and a "bell" forming part of the communication between said ear-tubes and said receiver, and detachably connected with the latter, substantially as described.

2. A binocular stethoscope comprising a diaphragm-receiver as provided with the right sound-conducting tube b, the "bell" c, a rigid tube e inserted into the mouth of said "bell" and detachably connected therewith, a flexible tube d connecting the rigid tube c with the sound-conducting tube of the receiver, and ear-tubes in communication with said "bell," substantially as described.

700,729. CHAIN-PUMP. LEO A. BRIGGS, Chatham, Ohio, assignor, by license assignment, to Leo A. Briggs, Jr., and Edward J. Briggs, trading under firm-name of Chatham Pump Company, Chatham, Ohio. Filed Sept. 17, 1903. Serial No. 601,578. (No model.)

Claim.—A tube having a longitudinal cam extending along one side and forming an exterior discharging-rib, and having at its opposite side an outwardly-bent portion forming a longitudinal strengthening-rib within the tube and also forming inside the tube a longitudinal channel, substantially as set forth.

700,730. CIRCULAR-KNITTING MACHINE. HENRY BRUNTON, Philadelphia, Pa. Filed Oct. 25, 1900. Serial No. 706,043. (No model.)

Claim.—1. In a knitting-machine, the combination with the bed-plate and the needle-cylinder, of a support for the latter provided with clamping-jaws, and a shaft provided with an eccentric portion interposed longitudinally between the edges of said jaws, substantially as described.

2. In a knitting-machine, the combination with the bed-plate and the needle-cylinder, of a support for the latter, comprising a ring provided with a projecting upper portion split vertically and horizontally to afford two expansible jaws, and a vertical shaft journaled in the lower portion of the ring and extended between the opposing edges of said jaws, each extended portion being fastened to afford an elongated eccentric or cam, substantially as described.

3. The combination with the cam-carrier, its knitting-cams, a normally active depressing-pickup, and a normally active elevating-pickup, of a movable member mounted on said carrier and adapted to engage and render inactive the depressing-pickup, and to release the same and permit it to return to action, and a yielding latch on said member adapted to be moved thereby into and from the path of the elevating-pickup, substantially as described.

4. The combination with the cam-carrier, its knitting-cams, a normally active depressing-pickup, and a normally active elevating-pickup, of a movable member mounted on said carrier and adapted to engage and render inactive the depressing-pickup, and to release the same and permit it to return to action, a vibratory latch or dog pivoted on said member and movable thereby into and from the path of the elevating-pickup, and a spring to maintain said latch or dog in a normal position in respect to said member, substantially as described.

5. The combination with the cam-carrier, its knitting-cams, a normally active depressing-pickup, and a normally active elevating-pickup, of a slide on said carrier adapted to engage and render inactive the depressing-pickup, and to release the same and permit it to return to action, and a yielding latch on said member adapted to be moved thereby into and from the path of the elevating-pickup, a rock-shaft, and a connection between the same and said slide, substantially as described.

6. In a knitting-machine, the combination, with a cam-carrier, its knitting-cams, a set of normally active depressing-pickups, and a set of normally active elevating-pickups, of two oppositely-movable slides one of which is provided with portions which coast with and control the active and inactive positions of one pickup of each set, and the other of which slides is provided with a portion which controls the active and inactive positions of the remaining depressing-pickup, and with a yielding latch or dog which is movable into and from the path of the remaining elevating-pickup, together with means for actuating said slides, substantially as described.

7. In a knitting-machine, the combination with a cam-carrier, of two oppositely-actuated cams thereon movable in a horizontal plane into and from the interior of the carrier, outwardly-extending stems on said cams, springs to maintain the same normally retracted, and a rocking head movable in a vertical plane and provided on its inner face with berths or cam portions which take against the outer ends of the respective stems, substantially as described.

8. In a knitting-machine, the combination with the cam-cam, of two oppositely-inclined cams thereon movable into and from the interior of the carrier, outwardly-extending stems on said cams, springs to maintain the cams normally retracted, and a rocking head movable in a plane at right angles to the path of said cams and provided on its inner face with bevels or cam portions which take against the outer ends of said stems, a fixed cam adapted to coast with said head to set it in a neutral position, a tappet-arm on said head, trip mechanism, and means whereby it may be moved into and from the path of said cam, substantially as described.

9. In pattern mechanism for knitting-machines, the combination with a rock-shaft, and means for actuating the same, of two independently-movable ratchet-wheels thereon, pattern devices adapted to be intermittently actuated by said wheels, arms affixed to said shaft carrying pawls adapted to coast with the respective wheels, and means whereby the said pawls may be moved into and out of action in alternate succession.

10. In pattern mechanism for knitting-machines, the combination with a rock-shaft, and means for actuating the same, of two independently-movable ratchet-wheels thereon, pattern devices adapted to be intermittently actuated by said wheels, arms affixed to said shaft carrying pawls adapted to coast with the respective wheels, rock-levers loosely mounted on said shaft and provided with cam-like arms movable below and from the respective pawls to render the latter idle and active in alternate succession, and means for shifting said levers in opposite directions to each other at predetermined intervals.

11. In pattern mechanism for knitting-machines, the combination with a rock-shaft, and means for actuating the same, of two independently-movable ratchet-wheels thereon, pattern devices adapted to be intermittently actuated by said wheels, arms affixed to said shaft carrying pawls adapted to coast with the respective wheels, rock-levers loosely mounted on said shaft and provided with cam-like arms movable below and from the respective pawls to render the latter idle and active in alternate succession, reciprocating slides, a rock-lever connected with said slides and adapted to move them longitudinally in opposite directions to each other, and means for operating said lever.

12. In a knitting-machine provided with narrowing and widening mechanism, the combination with the needle-cylinder, the cam-cylinder, the driving-shaft geared with the latter, flat and loose pulleys on said shaft, a driving-belt, a skipper therefor, means whereby said skipper is held normally adjacent to the loose pulley, means whereby it may be temporarily held adjacent to the flat pulley, a reciprocating rotary mechanism, gearing between the same and the flat pulley, a clutch whereby the said reciprocating mechanism and the flat pulley may be thrown into and out of action in respect to the shaft in alternate succession, means whereby said clutch normally locks the flat pulley to the shaft, a latch device whereby said clutch may be temporarily engaged with the reciprocating mechanism, a rock-shaft, means for actuating the same, two independently-movable ratchet-wheels on said rock-shaft, pattern mechanism adapted to be intermittently actuated by said wheels, arms on said rock-shaft carrying pawls adapted to coast with the respective wheels, oppositely-movable devices coasting with said pawls to render the latter active and idle in alternate succession, operative connections between said devices and the clutch, operative connections between said latch device and one of said pattern mechanism, and trip devices between the other pattern mechanism and the skipper mechanism.

13. In a knitting-machine, provided with narrowing and widening mechanism, the combination with the needle-cylinder, the cam-cylinder, the driving-shaft geared with the latter, flat and loose pulleys on said shaft, a driving-belt, a skipper therefor, means whereby said skipper is held normally adjacent to the loose pulley, a pinion fixedly connected with the latter pulley, a secondary shaft, a wheel on the latter geared with said pinion, a crank on said secondary shaft, a radius-bar connected therewith carrying a sector, a pinion loosely mounted on the main shaft and geared with said sector, a clutch, means whereby it is normally held in position to lock the flat pulley to the shaft, a latch device whereby said clutch may be temporarily engaged with the pinion last named, a trip device for the skipper, a trip device for the said latch, and pattern mechanism for actuating said trip devices at predetermined intervals.

14. In a knitting-machine, provided with narrowing and widening mechanism, the combination with the needle-cylinder, the cam-cylinder, the driving-shaft geared with the latter, flat and loose pulleys on said shaft, a driving-belt, a skipper therefor, means whereby said skipper is held normally adjacent to the loose pulley, a pinion fixedly connected with the latter pulley, a counter-shaft, a wheel on the latter geared with said pinion, a crank on said counter-shaft, a radius-bar connected therewith carrying a sector, a pinion loosely mounted on the main shaft and geared with said sector, a clutch, means whereby it is normally held in position to lock the flat pulley to the shaft, a latch device whereby said clutch

may be temporarily engaged with the pinion last named, a rock-shaft, operative connections between the same and the radius-bar, independently-movable ratchet-wheels on said rock-shaft, pattern mechanism adapted to be intermittently actuated by said wheels, arms on said rock-shaft carrying pawls adapted to coast with the respective wheels, means for rendering said pawls active and inactive in alternate succession, operative connections between said latch and one of said pattern mechanism, and trip devices between the other pattern mechanism and the skipper mechanism.

15. In a knitting-machine, the combination with the cam-cylinder and the needle-cylinder having provision for vertical adjustment, of a driving-shaft, gearing between the same and the cam-cylinder, means for imparting continuous rotary movement to said shaft, means for imparting reciprocating rotary movement to said shaft, a clutch member whereby either of said means may be thrown into or out of action in respect to the shaft, as desired, a hand-lever for controlling said clutch member, a rock-shaft connected therewith, and adapted to be rocked thereby, a vertically-swinging lever constructed and arranged to effect the adjustment of the needle-cylinder, and means on said rock-shaft coasting with said lever to control the position thereof when the rock-shaft is actuated.

16. In a knitting-machine, the combination with the cam-cylinder, the needle-cylinder, and a vertically-movable support for the latter cylinder, of a driving-shaft, gearing between the same and the cam-cylinder, means for imparting continuous rotary movement to said shaft, means for imparting reciprocating rotary movement to said shaft, mechanism whereby either of said means may be rendered active or inactive in respect to the shaft, a lever adapted to coast with the movable support, a rock-shaft, a link connection between the same and the said lever, and mechanism for actuating said shaft at predetermined intervals.

17. In a knitting-machine, the combination with the cam-cylinder, the needle-cylinder, and a vertically-movable support for the latter cylinder, of a driving-shaft, gearing between the same and the cam-cylinder, means for imparting continuous rotary movement to said shaft, means for imparting reciprocating rotary movement to said shaft, mechanism whereby either of said means may be rendered active or inactive in respect to the shaft, a lever adapted to coast with the movable support, a rock-shaft, an adjustable arm on one end of said shaft, means for adjusting the same, a connection between said arm and the lever, and pattern mechanism for actuating said rock-shaft at predetermined intervals.

18. In a knitting-machine provided with narrowing and widening mechanism, the combination with the needle-cylinder, the cam-cylinder, the driving-shaft geared with the latter, flat and loose pulleys on said shaft, a driving-belt, a skipper therefor, means whereby said skipper is held normally adjacent to the loose pulley, means whereby it may be temporarily held adjacent to the flat pulley, a reciprocating rotary mechanism, gearing between the same and the flat pulley, a clutch whereby the said reciprocating mechanism and the flat pulley may be thrown into and out of action in respect to the shaft in alternate succession, means whereby said clutch normally locks the flat pulley to the shaft, a latch device whereby said clutch may be temporarily engaged with the reciprocating mechanism, a trip device for the skipper, a trip device for the said latch, and pattern mechanism for actuating said trip devices at predetermined intervals, together with means for temporarily locking the clutch in idle position.

700,781. CORN-PLANTER. GEORGE W. BRYAN, Springfield, Ohio. Filed Sept. 24, 1902. Serial No. 26,892. (No model.)

Claim.—1. In a corn-planter, the combination, with a main frame structure provided with supporting and covering wheels, of a draft-pole rigidly secured to said frame structure, an auxiliary frame carrying furrow-opening and seed-dropping devices and pivotally connected at its front end with the frame structure, a lever mounted on the frame structure, and connecting means between said lever and the auxiliary frame for raising and lowering said auxiliary frame, said connecting means comprising a spring, substantially as described.

2. In a corn-planter, the combination with a pair of wheels, of a main shaft mounted therein, a frame structure carried by said main shaft, a tongue fixedly connected with said frame structure, a frame carrying dropper mechanism and pivoted at its forward end to said frame structure, a spring connected with said frame structure at its forward end, a pivoted bar carried by said frame structure, a lever connected with said bar, a link connected with said spring and with said bar, whereby when said lever is raised and lowered said spring is also raised and lowered, and means for fixedly connecting said dropper-mechanism frame with said spring, all substantially as shown and described.

3. In a corn-planter, the combination with supporting-wheels, of an axle rotated by said supporting-wheels, a frame structure mounted on said axle having a pole fixedly connected therewith, a frame carrying dropper mechanism and pivoted at its forward end to said frame structure, a pair of spring-bars, one end of each of which is also secured to said frame

structure, means for fixedly connecting said spring-bars with said dropper-mechanism frame, and adjustable means for connecting the inner ends of said spring-bars with said frame structure, whereby said dropper mechanism may also be adjusted, all substantially as shown and described.

4. In a corn-planter, the combination with a pair of supporting and driving wheels, of a main shaft mounted in said wheels and operated thereby, a frame structure supported by said shaft, a pivoted cross-bar also supported by said shaft having a pair of arms extending forward therefrom, and a foot-lever extending backward therefrom, a frame carrying dropper mechanism and pivoted at its forward end to said frame structure, a pair of springs connected with said frame structure at their forward ends, means for rigidly connecting said dropper-mechanism frame with said springs, a pair of links connected with the respective spring-bars and also with the respective arms, and a hand-lever also connected with said cross-bar, whereby said spring-bars may be raised and lowered by hand, and also by foot-power, all substantially as shown and described.

5. In a corn-planter, the combination with a frame structure, of a pair of spring-bars connected thereto at their forward ends, a frame carrying dropper mechanism and pivoted to said frame structure at its forward end, means for rigidly connecting said dropper-mechanism frame with said spring-bars, a dropper-shaft and a valve-operating shaft carried by said dropper mechanism, means for operating said dropper-shaft, means carried by said dropper-shaft for operating said valve-operating shaft, and a hand-lever connected with said spring-bars for elevating and lowering said dropper-mechanism frame, all substantially as shown and described.

6. In a corn-planter, the combination, with a main frame structure, provided with a rotating axle having supporting and covering wheels, and a draft-pole rigidly secured to said frame structure, of an auxiliary frame provided with furrow-opening and seed-dropping devices and pivotally connected at its front end to the main frame structure, means mounted on the main frame structure for raising and lowering said auxiliary frame, check-rod and hand operating devices carried by the auxiliary frame for actuating the seed-dropping mechanism, connecting mechanism between the main axle and the seed-dropping mechanism whereby the latter may be operated from the former, and means for throwing said connecting mechanism into and out of operation, substantially as described.

7. In a corn-planter, the combination with a dropper-shaft, of a lever, means for connecting said lever with said dropper-shaft to operate said shaft in one direction, said lever having a ball-and-socket joint therein and a bifurcated end, a pair of rollers, a check-rod wire adapted to pass over said rollers and through the bifurcated end of said lever, and means for swinging said rollers and said bifurcated lever out of contact with said check-rod wire, all substantially as shown and described.

8. In a corn-planter, the combination with dropper mechanism, a dropper-shaft rotatably mounted therein, a lever pivotally supported thereby, said lever having to upper and bifurcated, a ball-and-socket joint in said bifurcated lever, whereby said bifurcated lever may rotate, a pivoted frame structure, a pair of rollers carried thereby, a check-rod wire adapted

to pass over said rollers and through the bifurcated end of said lever, and means for holding said roller-frame in wire-supporting position and for releasing said roller-frame, whereby said rollers will swing out of wire-supporting position, at the same time the bifurcated end of said lever rotating to also release said check-rod wire, all substantially as shown and described.

9. In a corn-planter, the combination with a dropper mechanism, of a check-rod device mounted at each end of said dropper mechanism, a pivoted bifurcated lever carried by said check-rod device having a ball-and-socket joint therein, a roller-frame pivoted to said check-rod device, a pair of rollers carried thereby, a check-rod wire adapted to extend over said rollers and be supported thereby and extend through the bifurcated end of said lever, a trip device for holding said roller-frame in position for said wheels to support said wire and for releasing said roller-frame, whereby said rollers, as also said bifurcated lever, disengage from said check-rod wire, said lever being operated in one direction by said check-rod wire, and a spring for operating said lever in the opposite direction, all substantially as shown and described.

10. In a corn-planter, the combination, with a main frame structure provided with longitudinally-slotted bearings, of supporting and covering wheels provided with a rotating axle mounted in said bearings, an auxiliary frame carrying furrow-opening and seed-dropping devices and pivoted at its front end to the main frame structure, and operating mechanism connecting said seed-dropping devices and the axle, the said axle being mounted to yield longitudinally in its bearings, and springs for returning said axle to its normal position, substantially as described.

11. In a corn-planter, the combination with a pair of carrying-wheels having a main axle mounted therein and adapted to rotate therewith, of a frame structure having yieldable bearings within which said main axle is mounted, dropper mechanism pivoted to said frame structure, a dropper-shaft carried by said dropper mechanism, a sprocket-wheel mounted thereon, a sprocket-wheel mounted on said main axle, a sprocket-chain for connecting said sprocket-wheels with each other, said bearings yielding to permit said dropper mechanism to also yield without unduly stretching said sprocket-chain, all substantially as shown and described.

12. In a corn-planter, the combination with a pair of carrying-wheels having a main axle mounted therein, a frame structure mounted on said axle, a pivoted shaft carried by said frame structure, a pair of arms projecting from said shaft in a forward direction, and a foot-lever projecting from said shaft in a rearward direction, a hand-lever secured to said pivoted shaft, a toothed segment, a pawl carried by said hand device engaging with said toothed segment for holding said hand device in any desired position, whereby said pivoted bar is held in any desired position, dropper mechanism, a pair of spring-bars secured to said frame structure at one end and connected with said arms at their other ends, and means for rigidly connecting said dropper-shaft with said spring-bars, whereby when said foot-lever and said hand-lever are operated said dropper mechanism is elevated or lowered, all substantially as shown and described.

700,782. PLANIMETER. RICHARD W. BRYAN, Southport Hill, England. Filed Oct. 5, 1901. Serial No. 78,000. (No model.)

Claim.—1. A planimeter comprising a tracing-arm, an index-roller, and means for automatically varying the inclination of the axis of the said index-roller to the said tracing-arm to compensate for variation in a diagram-track.

2. A planimeter comprising a pivotally-mounted tracing-arm, means for guiding the pivot of the said arm rectilinearly, an index-roller connected to the said tracing-arm so as to be moved partly rectilinearly and partly radially therewith, and means for automatically varying the inclination of the axis of the said index-roller to the said tracing-arm to compensate for variation in a diagram-track.

3. A planimeter comprising a pivotally-mounted tracing-arm, means for guiding the pivot of the said arm rectilinearly, an index-roller connected to the said tracing-arm so as to be moved partly rectilinearly and partly radially therewith, and a cam for varying the inclination of the axis of the said index-roller to the said tracing-arm to compensate for variation in a diagram-track.

4. A planimeter comprising a pivotally-mounted tracing-arm, means for guiding the pivot of the said arm rectilinearly, an index-roller connected to the said tracing-arm so as to be moved partly rectilinearly and partly radially therewith, and a cam and a spring for varying the inclination of the axis of the said index-roller to the said tracing-arm to compensate for variation in a diagram-track.

5. A planimeter comprising a pivotally-mounted tracing-arm, means for guiding the pivot of the said arm rectilinearly, a planimeter-arm connected to the said tracing-arm so as to move therewith about the pivotal axis thereof, a frame or holder joined to the said planimeter-arm, an index-roller mounted in the said frame or holder, and means for varying the inclination of the axis of the said index-roller to the said planimeter-arm to compensate for variation in a diagram-track.

6. A planimeter comprising a pivotally-mounted tracing-arm, means for guiding the pivot of the said arm rectilinearly, a planimeter-arm connected to the said tracing-arm so as to move therewith about the pivotal axis thereof, a frame or holder joined to the said planimeter-arm, an index-roller mounted in the said frame or holder, and a cam for varying the inclination of the axis of the said index-roller to the said planimeter-arm to compensate for variation in a diagram-scale.

7. A planimeter comprising a pivotally-mounted tracing-arm, means for guiding the pivot of the said arm rectilinearly, a planimeter-arm connected to the said tracing-arm so as to move therewith about the pivotal axis thereof, a frame or holder joined to the said planimeter-arm, an index-roller mounted in the said frame or holder, and a cam and a spring for varying the inclination of the axis of the said index-roller to the said planimeter-arm to compensate for variation in a diagram-scale.

8. A planimeter comprising a tracing-arm, a rectilinearly-guided frame or carrier to which the said arm is pivoted, a planimeter-arm carried by the said frame or carrier, an index-roller, a frame or holder in which the said roller is mounted, means for varying the inclination of the said frame or holder to the said planimeter-arm, and wheels on which the said frame or carrier is and which are arranged on opposite sides thereof.

700,788. POCKET-SPITTOON. RICHARD BUNYER, Brooklyn, and JAMES HARR, New York, N. Y. Filed Sept. 7, 1901. Serial No. 74,000. (No model.)

Claim.—1. A pocket-spittoon having a lid, a hook on the lid, a hinged valve, and a rearwardly-projecting arm on said valve which is adapted to be engaged by the hook, substantially as specified.

2. A pocket-spittoon having an annular body, a flexible bag secured to the lower side thereof, a lid for closing the annular body, a valve for closing the bag, a spring-hook on the lid, and a rearwardly-projecting arm on the valve which is adapted to be engaged by said hook, substantially as specified.

700,784. BURIAL-Vault. ALVAN R. BURKE, Salem, Mass. Filed Sept. 24, 1901. Serial No. 73,998. (No model.)

Claim.—1. A concrete burial-vault having an extended portion integral with a wall, a conduit formed within said extended wall establishing communication between the interior and exterior of the vault, and a check-valve in said conduit for preventing the ingress of foreign matter into said vault through said conduit.

2. A concrete burial-vault having an integral upward extension above one wall terminating at the level of the ground, a conduit located within said extension and the wall, extending upward from the interior of said vault into the extension and thence downward through the wall, and terminating at the exterior of the wall near the bottom thereof, and a check-valve located within said conduit, substantially as described.

700,785. APPARATUS FOR WASHING COAL, COKE, &c. CURTIS B. BUNYER, Chicago, near Durham, England. Filed Apr. 18, 1901. Serial No. 65,000. (No model.)

Claim.—1. In a coal-washing apparatus in which the heavy impurities or dirt are discharged at the higher end of the slope of a sloping endless belt moving toward that end while the washed coal is floated down toward the other end, a dip in said belt near the last-named end for causing the washing-water to be there comparatively at rest, in order that the fine parts of the washed coal held in suspension, may deposit there in combination with means for raising the washed coal from said dip, substantially as set forth.

2. In a coal-washing apparatus in which the dirt or heavy impurities are discharged at the upper end of a sloping endless belt, having motion toward said end, a trough in which said belt travels, means for washing the coal and floating the washed coal down the slope of the belt, a dip in said belt at or near the lower end of its slope, and means for raising the washed coal from said dip, substantially as and for the purpose set forth.

3. In a coal-washing apparatus, the combination of a sloping endless belt, a trough in which said belt has motion toward the higher end of the slope, means on the lower or under side of the belt for coupling said trough, means near the higher end of the slope of the belt for supplying coal and water thereto in regulated quantities, and a receptacle of

said higher end of the belt for receiving the impurities, substantially as set forth.

4. In a coal-washing apparatus the combination of a sloping endless belt moving toward the higher end of the slope means near that end for supplying coal and water in regulated quantities to the upper web of the belt, a set of transversely-arranged valves at the coal-supply end and another set of such valves between said end and the water-supply end substantially as and for the purpose set forth.

5. In a coal-washing apparatus the combination of a sloping endless belt moving toward the higher end of the slope, a dry-coal-supply hopper, near that end with means for regulating the delivery of coal therefrom a feed-plate or trough receiving the coal from the coal-hopper, a water-supply tank nearer that end, a pipe therefrom with regulating-cock and cut-cocks which discharge washing-water onto the coal in said feed-trough, another pipe from said supply-tank with regulating-cock and cut-cocks which discharge washing-water onto the belt nearer the water-tank, a set of transversely-arranged valves at the coal-supply end and another set of such valves between the two water-supply ends, substantially as and for the purpose set forth.

6. In a coal-washing apparatus the combination of a sloping endless belt moving toward the higher end of the slope, means substantially as described near that end for supplying coal and water in regulated quantities to the upper web of the belt, a dip in the belt at the other end of the belt, a trough at said dip, a settling-wall for receiving from the lower end of the slope of the belt the overflow water with matter suspended therein, an elevator for raising the slurry therefrom and delivering it into the belt for being re-washed, a pump-well receiving the overflow water from the settling-wall, a pump to convey the water therein to the water-supply tank, and an overflow-pipe from the latter to the pump-well substantially as set forth.

7. In a coal-washing apparatus, the combination of the sloping endless belt moving toward the higher end of the slope, means for delivering coal to said belt near the said higher end of the slope, means for supplying water to the belt and floating the coal down the slope, an elevator near the bottom of said slope for raising the washed coal from the belt, said elevator having a hinged bottom riding on said belt and a settling-wall for receiving from the lower end of the slope the overflow-water and matter held in suspension therein, substantially as and for the purpose set forth.

8. In a coal-washing apparatus, a sloping endless belt having motion toward the higher end of the slope, means for feeding the coal to be washed to said belt at or near said higher end, a dip in the belt near the lower end of the slope causing the wash-water to be there comparatively at rest; in combination with an elevator for raising the washed coal from said dip, and means for adjusting the height of the elevator relatively to the dip, substantially as and for the purpose set forth.

700,786. MILLING-MACHINE CUTTER. JOHN F. CAGELL, Baltimore, Md., assignor to C. H. Margenthaler Company, Baltimore, Md., a Corporation of Delaware. Filed May 14, 1901. Serial No. 65,577. (No model.)

Claim.—1. In a milling-cutter the combination of a body-piece having a series of longitudinal channels on its outer surface, longitudinally-adjustable cutting-blades within said channels and having their cutting edges extending outwardly beyond the periphery of the body-piece, each blade having a plain beveled surface on its forward side, and locking-curveds extending into the body and having tapering portions adapted to engage the beveled surfaces of the blades.

2. In a milling-cutter the combination of a body-piece having a series of longitudinal channels on its outer surface, longitudinally-adjustable cutting-blades within said channels and having their cutting edges extending outwardly beyond the periphery of the body-piece, each blade having a base projecting forwardly from the blade, said base having a plain beveled surface on its forward side, and locking-curveds extending into the body and having tapering portions adapted to engage the beveled surfaces of the blades.

3. In a milling-cutter, the combination of a body-piece having a series of longitudinal channels on its outer surface, longitudinally-adjustable

cutting-blades in said channels, and adjusting-curveds extending longitudinally into the body-piece adjacent to the blades, said curveds and blades being connected to mutually engage, whereby the blades may be adjusted in either direction by turning the curveds.

4. In a milling-cutter, the combination of a body-piece having a series of longitudinal channels on its outer surface, longitudinally-adjustable cutting-blades in said channels, each blade having a transverse groove on its rear side near one end, and adjusting-curveds extending longitudinally into the body in the rear of the blades, each curved having a flange engaging the slot in an adjacent blade.

5. In a milling-cutter, the combination of a body-piece having a series of channels on its outer surface, cutting-blades in said channels, each having a plain beveled surface on one side and a transverse groove near one end, adjusting-curveds extending longitudinally into the opposite ends of the body adjacent to the blades, each adjusting-curved having a head engaging the groove in the adjacent blade, and locking-curveds having tapering heads adapted to engage the beveled surfaces of the blades.

6. In a milling-cutter, the combination of a body-piece having a series of longitudinal channels on its outer surface, adjustable cutting-blades within said channels, each blade having a plain beveled surface on one side and a transverse groove near one end, adjusting-curveds extending longitudinally into the body adjacent to the blades, each adjusting-curved having a flange engaging the groove in the adjacent blade, and locking-curveds having tapering heads adapted to engage the beveled surfaces of the blades.

7. In a milling-cutter, the combination of a body-piece having a series of longitudinal channels on its outer surface, cutting-blades in said channels, each blade having a transverse groove near one end, the consecutive blades having their grooved ends at opposite ends of the body-piece, and adjusting-curveds extending longitudinally into the body-piece adjacent to the blades, each curved having a flange engaging the transverse groove in the adjacent blade.

8. In a milling-cutter, the combination of a body-piece having a series of longitudinal channels on its outer surface, cutting-blades in said channels, each blade having a plain beveled surface on one side and having a transverse groove near one end, and the consecutive blades having their grooved ends lying at opposite ends of the body, adjusting-curveds extending longitudinally into the body adjacent to the blades each curved having a flange engaging the groove in the adjacent blade, and locking-curveds having tapering heads adapted to engage the beveled surfaces on the blades.

9. A longitudinally-adjustable milling-cutter blade having a transverse groove or recess near one end and a base projecting forwardly from the blade, said base having a continuous beveled face 4 on its forward side, substantially as described.

700,787. METAL GATE. WILLIAM R. CANTRELL, Chicago, Ill., assignor to Frank A. Anderson, Chicago, Ill. Filed Feb. 12, 1902. Serial No. 65,757. (No model.)

Claim.—1. A gate comprising the ribbed metal stile, each stile having its upper and lower ends bent horizontally and laterally away from the body of the gate and constituting retainers for pin-like supports, a series of tension-wires uniting the stiles, and a ribbed metal strut having one end forked into upwardly and downwardly bent branches, substantially as described.

2. In a gate the combination of two ribbed metal stiles, each stile having its upper and lower ends bent laterally and vertically perforated, a series of tension-wires uniting said stiles and a ribbed metal strut having one end forked into upwardly and downwardly bent branches secured to one of the stiles, substantially as described.

3. In a gate, the combination of two ribbed metal stiles, each stile having its upper and lower ends bent laterally and vertically perforated, a series of tension-wires uniting said stiles and a ribbed metal strut secured to said stiles, with gate-supporting posts and a gravity-latch pivoted to one of said posts and having its lower end over the lateral extension of the stile, substantially as described.

700,788. SCREW-BOARD. JOHN B. CARTER, Council Bluffs, Ark. Filed Aug. 28, 1901. Serial No. 73,766. (No model.)

Claim.—A device of the class described comprising a casing provided in its front with apertures and having open bearing-recesses at opposite sides, said casing being also provided with an intermediate bar having opposite bearings, the ribbon-receiving rolls arranged in pairs and provided with inner and outer journals arranged in the said bearings and in the bearing-recesses, the removable front arranged in suitable ways of the sides of the casing, the independently-movable rolls having inner and outer journals detachably arranged in the bearings of the intermediate bar and in the bearing-recesses, the elastic bands arranged on the outer journals and frictionally engaging the inner and the walls of the open outer bearing-recesses and retaining the rolls in their adjusted positions and permitting the same to be released when sufficient force is applied, a cord-holder mounted on the casing, and a guide arranged at the front of the casing and having a slide, substantially as and for the purposes described.

700,789. ADJUSTABLE DRUM-CHART. JENNIE H. GOSWORTHY, Fall River, Mass. Filed Dec. 12, 1901. Serial No. 86,728. (No model.)

Claim.—1. A form for drafting a bedrock-front, comprising the main template A having the notch *a'* and the slots *a*, *a'*, *a''*, the plate A' having arms *a''* *a'''* slidably connected with the plate A and having the slots *a''* *a'''*, the plate B, pivoted to the plate A and having the slot *b*, and the graduated *b'*, the plate B' having the slots *b'*, *b''* and slidably connected with the plates A' and B', the plate C slidably connected with the plate A by the slots *a''*, the plate D slidably transverse on the plate D, the plate F slidably in the slot *c'* and pivotally connected with the plate B, the plate G pivotally attached to the plate F, and the plate G' slidably attached to the plate G and the plate H, the slots *c'*, *c''* and *d* being graduated for best-measure, and the slot *b'* for waist-measure.

2. A form for drafting the back of a bodice, comprising the plate K, the plate K' slidably lengthwise thereon, the plate L slidably laterally on the plate K, the plate L' slidably lengthwise on the plate L, the plate M slidably laterally on the plate K and in a lengthwise direction on the

plate L, and the plate M', pivoted to the plate K' and slidably on the plate M, the adjustment of the plates L and M being according to best-measure.

3. A form for drafting sleeves for garments, comprising a concentric-shaped plate R, containing longitudinal slots *r*, *r'*, an elbow-shaped plate S having a longitudinal slot in each arm, two longitudinally-adjustable curved plates T, T', pivotally attached to the plate R and pivotally and adjustably to the plate S, a plate U pivoted to the pivot of the plate T, plates V, W, adjustable respectively along the plates S and U, and each provided with a lateral arm, said arms being adjustably connected to a short plate X constituting an adjustable extension of the plate V, and an L-shaped plate Y similarly adjustable on the plate W and having its lateral arm adjustably connected with the plate X.

700,740. HYDRAULIC-VALVE MECHANISM. WILLIAM F. COLE, Worcester, Mass., assignor to Fisker Elevator Company, Worcester, Mass. Filed Mar. 1, 1900. Serial No. 673,167. (No model.)

Claim.—1. In an elevator, the combination with the car, of motor means for running said car, controlling means adapted to be operated from the car, and an automatic quick-starting, slow-stopping device adapted to permit of a quick start and to regulate the suddenness of stopping whereby the car will be brought to rest gradually.

2. The combination with the main three-way valve, of means for opening and closing said valve in either direction, and automatic means for regulating the opening and closing movements at different rates of speed.

3. The combination with the main valve for controlling the passage of fluid under pressure, of means for opening and closing said valve, and automatically-operated quick-opening, slow-closing means connected with said main valve, whereby the speed of opening and the speed of closing the main valve are regulated within independent limits, substantially as described.

4. In a hydraulic elevator, the combination with a main valve, of a valve-motor, pilot-valve mechanism, and an opening and closing regulating means operated by movement of the main valve, whereby a quick opening and slow closing of the main valve are effected.

5. The combination with the main valve for controlling the passage of fluid under pressure, of motor means for opening and closing said main valve, secondary valve mechanism for controlling the motor means, and hydraulic opening and closing regulating means for automatically regulating the velocity at which the main valve may be opened and the velocity at which the main valve may be closed at independent rates, substantially as described.

6. In a hydraulic elevator, the combination with a main three-way valve which is adapted to be closed when in its middle position, of means for opening and closing said valve, and regulating means operated automatically by said main valve and adapted to accomplish a quick opening and slow closing of said valve.

7. The combination with a main valve for controlling the passage of fluid under pressure, of means for operating said valve, and means for regulating the speed of opening and the speed of closing the main valve at independent rates, comprising enlarged and contracted water-passages and automatic means for controlling the flow of fluid through said passages, substantially as described.

8. The combination with the main valve for controlling the passage of fluid under pressure, of means for opening and closing said valve, speed-regulating means comprising separate passages for the flow of fluid in the operations of opening and closing the main valve in either direction, and automatic means adapted to regulate the flow of fluid through said passages, whereby the mechanism of opening and closing the main valve in either direction can be regulated within independent limits.

9. The combination with the three-way valve which is adapted to

be closed when in its middle position, of means for opening and closing said valve, of an opening and closing regulator comprising fluid-passages through which fluid must flow when the main valve is moved, and automatic means for controlling the flow of fluid through said passages, whereby the velocity of opening and the velocity of closing of the main valve in either direction may be regulated at independent rates of speed.

10. In a device for controlling the rate of speed in opening and closing a three-way valve in either direction, the combination with a cylinder, having in connection therewith, a contracted passage and an enlarged passage, of automatically-operated valve mechanism adapted to close said enlarged passage to the flow of fluid upon one movement of the main valve and open said enlarged passage to the flow of fluid upon the other movement, whereby upon one movement the flow of fluid has a free passage and upon the other movement a restricted passage, substantially as described.

11. The device for controlling the speed of opening and closing a valve, comprising a cylinder having in connection therewith enlarged passages, means for alternately closing said passages to the flow of fluid upon the different movements of the main valve, and contracted passages through which the fluid may flow when the enlarged passages are closed, substantially as described.

12. The combination with a main three-way valve for controlling the supply and discharge of fluid under pressure, of means for opening and closing said valve in either direction, and automatic regulating means for offering to the force applied to move said valve, resistance, different as between different movements of the main valve, substantially as described.

13. The combination with a main three-way valve for controlling the passage of fluid under pressure, of means for opening and closing said valve in either direction, and automatic means for offering to the force applied to open and close the main valve a resistance, different as between the opening and closing movements of said valve, substantially as described.

14. The combination with an elevator-valve which is adapted to be closed when in an intermediate position and opened when moved in either direction from said position, a valve-actuating member connected to said valve for moving same, means for permitting comparatively free movements of said actuating member in either direction from an intermediate position, and for correspondingly restricting the speed at which said actuating member may be returned from its extreme position.

15. The combination with an elevator-valve which is adapted to be closed when in an intermediate position and opened when moved in either direction from said position, a valve-actuating member connected to said valve for moving the same, means for permitting comparatively free movements of said actuating member in either direction from an intermediate position, and for correspondingly restricting the speed at which said actuating member may be returned from either extreme position.

16. The combination with the main three-way valve for controlling the passage of fluid under pressure, of an automatic opening and closing regulating mechanism applied to the main valve independent of the opening-handle and operating means connected with the main valve independent of the opening-handle and operated by the movement of the main valve whereby the valve is closed in either direction more gradually than it is opened, substantially as described.

17. The combination with a three-way valve, of fluid-pressure operated motor means for moving said valve, means for controlling said fluid-pressure comprising a throttling-valve, means for automatically operating said throttling-valve which are connected to said main valve and are adapted to move said throttling-valve so that said main valve is moved faster from a closed to an open position than from an open to a closed position.

18. The combination with a three-way valve, of motive means for moving said valve, means for controlling said motive means, and automatic regulating means comprising enlarged and contracted passages and valve mechanism for said passages, whereby the velocity of movements of the main valve may be regulated at different rates, substantially as described.

19. The combination with a main valve, of a valve-motor for moving said valve, a pilot-valve for controlling the action of the valve-motor, a throttling-valve adapted to regulate the flow of fluid to and from the valve-motor at different rates of speed, and automatic operating mechanism for said throttling-valve, substantially as described.

20. The combination with a main hydraulic valve, of a valve-motor adapted to move the main valve, the secondary or pilot valve for controlling the direction of the flow of fluid to the valve-motor, and the throttling-valve applied to the parts of the pilot-valve and connecting mechanism to the main valve-motor, whereby the main valve may be opened more rapidly than it is closed, substantially as described.

21. The combination with a main valve, of a valve-motor for mov-

ing said valve, a throttling-valve on the supply-passage to the motor, and a throttling-valve on the discharge-passage from the motor, of connections between said throttling-valves, whereby when either passage is throttled the other passage is open, and connections to a reciprocating part of the main valve mechanism, whereby the throttling-valves are automatically operated, substantially as described.

22. In a device for controlling the speed of opening and closing a valve, the combination with a valve-cylinder provided with an enlarged supply-passage and an enlarged exhaust-passage, of valve-pistons to control said passages, connections between said pistons whereby the passages are alternately opened and closed, contracted passages which are open when said enlarged passages are closed, and means for operating said pistons, substantially as described.

23. The combination with the main hydraulic valve, of a valve-motor for opening and closing said valve, a pilot-valve for controlling the flow of motive fluid to the valve-motor, and a throttling-valve connected with the parts of the pilot-valve to regulate the flow of motive fluid to and from the valve-motor, and adapted to be automatically operated by the movement of the main valve to throttle that part of the pilot-valve through which fluid must flow to cause the motor to close the main valve and at the same time to open that part of the pilot-valve through which fluid would flow to cause the valve-motor to open the main valve, substantially as described.

24. The combination with a main valve, of a motor for moving said valve, a pilot-valve, and a throttling-valve having contracted passages continuously open to the supply and exhaust passages of the pilot-valve, and enlarged passages also open to said supply and exhaust, said enlarged passages adapted to be alternately closed by movements of the main valve, and valve-pistons and connections for closing said enlarged passages, substantially as described.

25. The combination with a main valve, of a valve-motor and a pilot-valve, of a throttling-valve applied to the supply and discharge parts of said pilot-valve and automatically operated by a connection to a reciprocating part of the main valve, whereby the main valve is opened more rapidly than it is closed, substantially as described.

26. The combination with a main valve, of a valve-motor for moving said valve, a pilot-valve for controlling the action of the valve-motor, and a throttling device on the supply and exhaust of the pilot-valve comprising a valve-cylinder provided with an enlarged supply-passage and an enlarged exhaust-passage, of valve-pistons for closing said passages, connections between said pistons whereby said passages are alternately opened and closed, and contracted passages which are open when either of said enlarged passages is closed, and connections to the main valve mechanism whereby the throttling device is automatically operated, substantially as described.

27. In an automatic throttling device, the combination with a throttling-valve, of the reciprocating mechanism of the main valve, and setting means for the throttling-valve comprising connections to a reciprocating part of the mechanism moved by the valve-motor, whereby a slight movement of the main valve near its middle position sets the throttling-valve, substantially as described.

28. In an automatic throttling device for a valve-motor, the combination with a valve-motor, of a throttling-valve, of a valve-stem, of a cam element engaging said valve-stem, and connections from a reciprocating part of the mechanism moved by the valve-motor to the cam element, substantially as described.

29. In an automatic throttling device for a valve-motor, the combination with a valve-motor, of a throttling-valve, of the throttling-valve stem, of a journalled cam element connected to said valve-stem, of a rod connected at one end to a reciprocating part of the mechanism moved by the valve-motor and at the other end adapted to engage the cam element, and means for guiding said rod, substantially as described.

700,741. ORS BUCKET, DUMPER, AND CRUTCH. LOUIS COLLIER, Grapeland, Cal., assignor of two-thirds to Alfred E. Farber, Grapeland, Cal., and Joseph H. Thrall, Wellington, Kans. Filed Feb. 4, 1902. Serial No. 68,664. (No model.)

Claim.—1. In combination with a hoisting means and a tilting bucket raised and lowered thereby, said bucket having a bottom suspended from its bottom, a fixed chute having a trap in the bottom thereof, means to operate the trap, a pivotally-mounted dump-section at the upper end of the chute, said dump-section having means to cooperate with the bottom and dump the bucket, and means to act the pivotal dump-section, substantially as described.

2. In combination with a hoisting means and a tilting bucket raised and lowered thereby, said bucket having a bottom suspended from the bottom, a chute, a pivotally-mounted dump-section at the upper end of the chute and having means to cooperate with the bottom and dump the bucket, a rock-shaft having a crank connected to the dump-section, and

provided further with a weighted arm to move the dump-section out of the path of the bucket, and means to move the dump-section into the path of the bucket, substantially as described.

3. In combination with a hoisting means and a tilting bucket raised and lowered thereby, a chute, a dump-section pivotally mounted at the upper end of the chute, said dump-section and bucket having coacting means to tilt the latter and dump its contents into the chute, a rock-shaft having a crank connected to the dump-section and a weighted arm to normally turn the dump-section out of the path of the bucket, and means, connecting the dump-section to a fixed point, to limit the play of the dump-section, substantially as described.

700,742. BOX OR PACKAGE. FRANK P. GERT, Marion, Pa. Filed Mar. 14, 1908. Serial No. 96,576. (No model.)

Claim.—1. A wrapper for chocolate and other commodities, the same comprising a sheet of absorbent material and a sheet of perforated paraffin-paper interposed between the commodity and the sheet of absorbent material, substantially as described.

2. A wrapper for chocolate and other commodities, the same comprising a compound sheet having an outer hard or glazed surface and an inner absorbent surface and a sheet of perforated paraffin-paper interposed between the commodity and the absorbent surface of the compound sheet, substantially as described.

700,748. MOTOR-VEHICLE. WALTER A. CROWDER, Chicago, Ill. Filed June 26, 1908. Serial No. 96,948. (No model.)

Claim.—1. In a motor-vehicle, the combination of a vehicle-frame comprising a transverse frame member, a reach which terminates short thereof and trans-rod or struts which connect said reach with said transverse frame member, a motor pivoted to said transverse frame member at one side and connected to the reach of the frame at its opposite side, substantially as described.

2. The combination with a vehicle-frame comprising a reach which terminates short of the axle and trans-rod or struts which connect said

reach with a transverse frame member; of a motor pivoted to said transverse frame member at one side and yieldingly connected to the end of the reach at its opposite side, substantially as described.

3. The combination with a vehicle-frame comprising a transverse frame member, a reach which terminates short of said transverse frame member and trans-rod or struts which connect said reach with said transverse frame member, of a motor pivoted to said transverse frame member at one side and yieldingly connected to the end of the reach at its opposite side, said connection comprising an arm on said motor and a head on the reach, a pin rigidly secured in one thereof which engages a hole or opening in the other and a cushion beneath the arm on said motor, substantially as described.

4. In a motor-vehicle, the combination of a vehicle-frame comprising an axle-support, a reach which terminates short of said axle-support and trans-rod or struts which connect said axle-support and said reach, an axle revolvably mounted in suitable bearings in said axle-support, a motor pivoted to said axle-support at one end and yieldingly connected to the end of the reach at its opposite end and flexible driving connection between said motor and said axle, substantially as described.

5. In a motor-vehicle, the combination of a vehicle-frame comprising an axle-support, an axle revolvably mounted therein, a reach which terminates short of said axle-support, and trans-rod or struts which connect said axle-support with said reach, arms on said axle-support, a motor pivoted to said arms at one end and yieldingly connected to the end of the reach at its opposite end, said connection comprising an arm on said motor, a head on said reach, a pin in one thereof which engages a hole or opening in the other and a cushion beneath the arm on said motor, and a flexible driving connection between said motor and said axle, substantially as described.

6. In a motor-vehicle, the combination of a revolvable axle, a motor pivotally supported at one end adjacent to said axle eccentrically thereto, a gear secured to said axle, a pinion which engages said gear, a shaft to which said pinion is secured and driving connection between said pinion-shaft and the motor-shaft consisting of a universal joint the transverse axis of which coincides with the pivotal axis of said motor, substantially as described.

7. In a motor-vehicle, the combination of a revolvable axle, a motor pivotally supported at one end adjacent to said axle eccentrically thereto, a gear secured to said axle, a pinion which engages with said gear, a shaft to which said pinion is splined, cushions against which the ends of said pinion shaft and flexible driving connection between said pinion-shaft and the motor-shaft, substantially as described.

8. In a motor-vehicle, the combination of a revolvable axle, a motor pivotally supported at one end adjacent to said axle eccentrically thereto, a gear secured to said axle, a pinion which engages said gear, a shaft to which said pinion is splined, cushions against which the ends of said pinion shaft and flexible driving connection between said pinion-shaft and

the motor-shaft consisting of a universal joint the transverse axis of which coincides with the pivotal axis of said motor, substantially as described.

9. In a motor-vehicle, the combination of a revolvable axle, a motor pivoted at one end adjacent to said axle concentrically thereto and yieldingly supported at its opposite end, a gear secured to said axle, a pinion which engages with said gear, a shaft to which said pinion is secured and flexible connection between said pinion-shaft and the motor-shaft, substantially as described.

10. In a motor-vehicle, the combination of a revolvable axle, a motor pivoted at one end adjacent to said axle concentrically thereto and yieldingly supported at its opposite end, a gear secured to said axle, a pinion which engages said gear, a shaft to which said pinion is secured and flexible driving connection between said pinion-shaft and the motor-shaft consisting of a universal joint the transverse axis of which coincides with the pivotal axis of said motor, substantially as described.

11. In a motor-vehicle, the combination of a revolvable axle, a motor pivoted at one end adjacent to said axle concentrically thereto and yieldingly supported at its opposite end, a gear secured to said axle, a pinion which engages with said gear, a shaft to which said pinion is splined, cushions against which the ends of said pinion abut and flexible connection between said pinion-shaft and the motor-shaft, substantially as described.

12. In a motor-vehicle, the combination of a revolvable axle, a motor pivoted at one end adjacent to said axle concentrically thereto and yieldingly supported at its opposite end, a gear secured to said axle, a pinion which engages with said gear, a shaft to which said pinion is splined, cushions against which the ends of said pinion abut and flexible driving connection between said pinion-shaft and the motor-shaft consisting of a universal joint the transverse axis of which coincides with the pivotal axis of said motor, substantially as described.

13. In a motor-vehicle, the combination of an axle-support, an axle revolvably mounted in suitable bearings therein, a motor pivoted upon said axle-support at one end concentrically to said axle, a gear secured to said axle, a pinion which engages said gear, a shaft to which said pinion is secured and flexible connection between said pinion-shaft and the motor-shaft, substantially as described.

14. In a motor-vehicle, the combination of an axle-support, an axle revolvably mounted in suitable bearings therein, a motor pivoted upon said axle-support at one end concentrically to said axle, a gear secured to said axle, a pinion which engages said gear, a shaft to which said pinion is secured and flexible connection between said pinion-shaft and the motor-shaft consisting of a universal joint the transverse axis of which coincides with the pivotal axis of said motor, substantially as described.

15. In a motor-vehicle, the combination of an axle-support, an axle revolvably mounted in suitable bearings therein, a motor pivoted upon said axle-support at one end concentrically to said axle, and yieldingly supported at its opposite end, a gear secured to said axle, a pinion which engages said gear, a shaft to which said pinion is secured and flexible connection between said pinion-shaft and the motor-shaft, substantially as described.

16. In a motor-vehicle, the combination of an axle-support, an axle revolvably mounted in suitable bearings therein, a motor pivoted upon said axle-support at one end concentrically to said axle and yieldingly supported at its opposite end, a gear secured to said axle, a pinion which engages said gear, a shaft to which said pinion is secured and flexible connection between said pinion-shaft and the motor-shaft consisting of a universal joint the transverse axis of which coincides with the pivotal axis of said motor, substantially as described.

17. In a motor-vehicle, the combination of a vehicle-frame comprising an axle-support, a reach which terminates short of said axle-support and trans-rod which connect said reach and said axle-support, a motor pivoted to said axle-support at one end and yieldingly connected to the reach of the vehicle at its opposite end, said connection comprising an arm on said motor, a head on the reach, a pin rigidly secured in one thereof which engages a hole or opening in the other and a cushion beneath the arm on said motor, an axle revolvably mounted in suitable bearings in said axle-support, a gear secured to said axle, a pinion which engages with said gear, a shaft to which said pinion is secured and flexible connection between said pinion-shaft and the shaft of the motor, substantially as described.

18. In a motor-vehicle, the combination of a vehicle-frame comprising an axle-support, a reach which terminates short of said axle-support and trans-rod which connect said reach and said axle-support, a motor pivoted to said axle-support at one end and yieldingly connected to the reach of the vehicle at its opposite end, said connection comprising an arm on the motor, a head on the reach, a pin in one thereof which engages a hole or opening in the other and a cushion on which the arm on the motor rests, an axle revolvably mounted in suitable bearings in said axle-support, a gear secured to said axle, a pinion which engages with said gear, a shaft to which said pinion is splined, cushions against which

the ends of said pinion abut and flexible driving connection between said pinion-shaft and the shaft of the motor, substantially as described.

700,744. ELASTIC-FLUID TURBINE. CHARLES E. CUNY, New York, N. Y., assignor, by mesne assignments, to Curtis Steam Turbine Company, a Corporation of West Virginia. Filed Jan. 12, 1898. Serial No. 694,378. (No model.)

Claim.—1. The sectional nozzle for elastic-fluid turbines herein described, consisting of a number of separate complete nozzle-sections each having a contracted throat, and a supply-chamber anterior to and larger than said throat, each section being brought close together at their discharge ends, whereby the several separate jets or streams merge into a substantially single jet or stream at the points of discharge, substantially as set forth.

2. The sectional nozzle for elastic-fluid turbines herein described, consisting of a number of separate complete nozzle-sections each having a contracted throat, a supply-chamber anterior to and larger than said throat, and a discharging portion posterior to said throat, said sections being brought close together at their discharge ends, whereby the several separate jets or streams merge into a substantially single jet or stream at the points of discharge, substantially as set forth.

3. The sectional nozzle for elastic-fluid turbines herein described, consisting of a number of separate complete nozzle-sections each having a contracted throat, a supply-chamber anterior to and larger than said throat, and a discharging portion posterior to and enlarging beyond said throat, each section being brought close together at their discharge ends, whereby the several separate jets or streams merge into a substantially single jet or stream at the points of discharge, substantially as set forth.

4. In an elastic-fluid turbine, a sectional nozzle consisting of a number of separate complete nozzle-sections each having a contracted throat, a supply-chamber anterior to and larger than said throat, and a discharging portion posterior to and enlarging beyond said throat, each section being brought close together at their discharge ends, whereby the several separate jets or streams merge into a substantially single jet or stream at the points of discharge, in combination with means for admitting the elastic fluid to or shutting it off from more or less of said nozzle-sections, substantially as set forth.

5. In an elastic-fluid turbine, a sectional nozzle consisting of a number of separate complete nozzle-sections each having a contracted throat, a supply-chamber anterior to and larger than said throat, and a discharging portion posterior to and enlarging beyond said throat, each section being brought close together at their discharge ends, whereby the several separate jets or streams merge into a substantially single jet or stream at the points of discharge, in combination with a number of separate supply-passages, a valve-case with ports for each separate passage, and a valve in each valve-case opening and closing said ports progressively, substantially as set forth.

6. In an elastic-fluid turbine, a delivery-nozzle comprising sections substantially alike in form and in angle of delivery and brought close together at their discharge ends, whereby the jets or streams from adjacent

sections merge into a substantially single jet or stream at the points of discharge, in combination with means for admitting the elastic fluid to or shutting it off from more or less of said sections, substantially as set forth.

7. In an elastic-fluid turbine, a delivery-nozzle comprising sections substantially alike in form and in angle of delivery and brought close together at their discharge ends, whereby the jets or streams from adjacent sections merge into a substantially single jet or stream at the points of discharge, in combination with a plurality of separate supply-passages extending back from said nozzle-sections, and means for admitting the elastic fluid to or shutting it off from more or less of said supply-passages, substantially as set forth.

8. In an elastic-fluid turbine, the combination with two or more shells having movable vanes and receiving the elastic fluid in succession, of a delivery-nozzle for each shell comprising sections substantially alike in form and in angle of delivery and brought close together at their discharge ends, whereby the jets or streams from adjacent sections merge into a substantially single jet or stream at the points of discharge, valves for admitting the elastic fluid to or shutting it off from more or less of the sections of each nozzle, and means for moving said valves coordinately, substantially as set forth.

9. In an elastic-fluid turbine, the combination with two or more shells having movable vanes and receiving the elastic fluid in succession, of a delivery-nozzle for each shell comprising sections substantially alike in form and in angle of delivery and brought close together at their discharge ends, whereby the jets or streams from adjacent sections merge into a substantially single jet or stream at the points of discharge, a plurality of separate supply-passages extending back from the sections of said nozzle, valves for admitting the elastic fluid to or shutting it off from more or less of the supply-passages of each nozzle, and means for moving said valves coordinately, substantially as set forth.

10. In an elastic-fluid turbine, the combination with two or more shells containing movable vanes and receiving the elastic fluid in succession, of delivery-nozzles of successively-greater cross-sectional area for the two or more shells, each of said delivery-nozzles comprising sections brought close together at their discharge ends, a plurality of supply-passages for the sections of each nozzle, valve mechanisms acting to open and close each supply-passages, each valve mechanism having successively a greater movement for the same degree of regulation, and means causing the valve mechanisms to work coordinately so that the two or more nozzles shall be proportionately opened and closed, substantially as set forth.

11. In an elastic-fluid turbine, the combination of a number of separate supply-passages and separate complete nozzle-sections proportioned for the degree of conversion of pressure into velocity required for condensing-work, and a number of separate supply-passages and separate complete nozzle-sections proportioned for the degree of conversion of pressure into velocity required for non-condensing work, and valves for closing the supply-passages to one set of nozzle-sections when the supply-passages to the other set of nozzle-sections are opened, substantially as set forth.

12. In an elastic-fluid turbine, the combination of a number of separate supply-passages and separate complete nozzle-sections proportioned for the degree of conversion of pressure into velocity required for condensing-work, and a number of separate supply-passages and separate complete nozzle-sections proportioned for the degree of conversion of pressure into velocity required for non-condensing work, valves for closing the supply-passages to one set of nozzle-sections when the supply-passages to the other set of nozzle-sections are opened, and a governing or controlling valve common to the supply-passages of both sets of nozzle-sections for controlling the admission of elastic fluid to the set of nozzle-sections in operation, substantially as set forth.

13. In an elastic-fluid turbine, a delivery-nozzle comprising a number of sections brought close together at their discharge ends, each having a throat and diverging side walls beyond the throat, each side wall being formed by partitions separating the sections which are thicker at the throats than at the discharge ends of the sections, substantially as set forth.

14. In an elastic-fluid turbine, separate supply-conduits leading from a source of fluid-supply under pressure to two or more expansion delivery-passages delivering the fluid to the same set of buckets, in combination with valve mechanism automatically actuated by a speed-governor for admitting the fluid to and excluding it from the supply-conduits in succession, the valve mechanism opening and closing each conduit successively by degrees, substantially as set forth.

15. In an elastic-fluid turbine, a nozzle the cross-sectional perimeter of whose throat is curved, said nozzle having a rectangular discharging end in combination with a rotating turbine-wheel, substantially as set forth.

16. In an elastic-fluid turbine, a nozzle whose throat has a curved cross-sectional perimeter and having expanding or diverging walls which gradually draw into a rectangular form at the discharging end of the nozzle, substantially as set forth.

17. In an elastic-fluid turbine, a sectional nozzle, the throats of the several sections having a curved cross-sectional perimeter, and the discharge ends being rectangular, in combination with a rotating turbine-wheel, substantially as set forth.

18. In an elastic-fluid turbine, a sectional nozzle, the throats of the several sections having a curved cross-sectional perimeter and opening into expansion delivery-passages whose diverging walls gradually draw into a rectangular form at their discharge ends, substantially as set forth.

700,745. KEATER, JAMES DANIEL and WILLIAM H. COOK, Chicago, Ill., assignors of one-third to H. S. BOSTON, Chicago, Ill. Filed July 13, 1901. Serial No. 66,139. (No model.)

Claim.—1. In a heater, the combination of a suitable base, an outer casing, an outer water-chamber within said casing and separated therefrom by a fire-space, said casing and outer water-chamber having corresponding removable vertical sections at one portion thereof, an inner water-chamber, a central fuel-magazine, and draft-regulating means.

2. In a heater, the combination of a suitable base, an outer casing having a curved front, substantially tangential sides, and a removable rectangular rear section, an outer water-chamber separated from said casing by a fire and having a removable rear section adapted to be removed after removal of the rear section of the casing, an inner water-chamber, a fuel-magazine, and draft-regulating means.

3. In a heater, the combination of a suitable base, an outer casing having a rectangular-shaped removable rear wall-section, an outer water-chamber separated from said casing by a fire-space and having a removable rear section provided with inwardly-projecting water-stubs, an inner water-chamber and fuel-magazine, and draft-regulating means.

4. In a heater, the combination of a suitable base, an outer casing having a removable rear section, an outer water-chamber within said casing and separated therefrom by a fire-space, said water-chamber having a removable rear section provided with inwardly-projecting water-stubs, an inner water-chamber with which said stubs conform and which is itself provided on its front side with water-stubs, and draft-regulating means.

5. In a heater, the combination of a suitable base, a circular grate oscillatory in a horizontal plane, an adjacent grate having a concavity receiving the adjacent portion of said circular grate and itself pivoted on a horizontal axis, an outer casing having a rectangular-shaped removable rear wall-section, an outer water-chamber having a rectangular-shaped removable rear section, said water-chamber being separated from said casing by a fire-space, a baffle-plate covering the rear portion of said fire, vertical partitions in said fire at the front ends of the forward projections of said baffle-plate, a smoke-stack connected with said fire beneath said baffle-plate, an inner water-chamber between which and said outer water-chamber the products of combustion may pass upwardly, space being preserved to permit the products of combustion to pass over the upper end of said inner water-chamber and downwardly through the front portion of said fire, a fuel-magazine, and draft-regulating means.

6. In a heater, the combination of a suitable base, a superimposed casing provided with a rectangular-shaped rear section, a circular grate oscillatory in one plane, a grate oscillatory in another plane and suitably mounted to revolve the adjacent portion of said circular grate, an outer water-chamber separated from said casing by a flue, a baffle-plate covering the rear portion of said flue, vertical partitions in said flue at the front ends of the forward projections of said baffle-plate, an inner water-chamber and fuel-magazine, a smoke-stack having one communication with said fuel-magazine and another with said flue beneath said baffle-plate, dampers regulating the passage from the fuel-magazine and from said flue to said smoke-stack, and a removable fire-pot located at the base of said magazine.

7. In a heater of the character described, the combination of a suitable base, a circular grate and a casing having a substantially straight rear edge, an outer casing having a removable rear section, an outer water-chamber separated from said casing by a flue-space, said water-chamber comprising two curved sections connected at their front portions and a rear rectangular-shaped section connected with the rear portions of said first-named sections, an inner water-chamber and fuel-magazine, a baffle-plate covering the rear portion of said flue, vertical partitions in said flue at the front ends of the forward projections of said baffle-plate and extending downwardly to near the base of the heater, space being preserved at the upper portion of said outer water-chamber to permit gases to pass over said chamber into said flue at the front portion thereof, a smoke-stack connected with said magazine and with the rear portion of said flue beneath said baffle-plate, and dampers regulating the passage from said magazine and said flue to said smoke-stack.

8. In a heater, the combination of a suitable base, a suitable casing and a central fuel-magazine chambered to receive water, a lower chamber being provided for supplying one hot-water circuit, and an upper chamber for supplying another circuit.

9. In a heater, the combination of a base, a grate, an outer casing, an outer water-chamber separated from said casing by a flue, a baffle-plate covering the rear portion of said flue, vertical partitions in said flue and extending from said baffle-plate to near the lower portion of the flue, a dome located some distance above said outer water-chamber and in communication therewith, an inner water-chamber and fuel-magazine, said inner water-chamber being in communication with said dome, a smoke-stack communicating with said magazine and with the rear portion of said flue beneath said baffle-plate, and dampers regulating the passage from said magazine and said flue to said smoke-stack.

10. In a heater, the combination of a base, a grate, an outer casing, an outer water-chamber separated from said casing by a flue, a baffle-plate covering the rear portion of said flue, vertical partitions in said flue and extending from said baffle-plate to near the lower portion of the flue, a dome located some distance above said outer water-chamber and in communication therewith, an inner water-chamber and fuel-magazine, said inner water-chamber being in communication with said dome and divided horizontally to afford a separate chamber at its base, a heating-circuit connected with said dome, an independent hot-water-supply circuit connected with said hot-water chamber, a smoke-stack having communication with said magazine and with said rear portion of the flue beneath the baffle-plate, and dampers controlling the passage from said magazine and said flue to said smoke-stack.

11. In a heater, the combination of a base, a casing provided with a removable rear section, an outer water-chamber separated from said casing by a flue and having a removable rear section, said rear section having a horizontal dividing-wall affording an independent lower chamber, a baffle-plate covering the rear portion of said flue, vertical partitions depending from said baffle-plate, a dome located above said water-chamber, an inner water-chamber and fuel-magazine, a smoke-stack having communication with said magazine and with the rear portion of said flue beneath said baffle-plate, and dampers controlling the passage from said magazine and said flue to said smoke-stack.

12. In a heater, the combination of a base, a grate, an outer casing, an outer water-chamber separated from said casing by a flue, an inner water-chamber provided peripherally with vertically-extending water-lugs and affording a fuel-magazine, a baffle-plate covering the rear portion of said flue, vertical partitions depending from said baffle-plate, a smoke-stack communicating with said fuel-magazine and with the rear portion of said flue beneath said baffle-plate and dampers controlling the passage from said magazine and said flue to said smoke-stack.

13. In a heater, the combination of a base, an outer casing, an outer water-chamber separated therefrom by a flue, a baffle-plate covering the rear portion of said flue, vertical partitions in said flue, a dome located above said water-chamber and communicating with said water-chamber, an inner water-chamber communicating with said dome, a separate water-chamber at the base of said inner water-chamber, pipes leading therefrom, a circuit connected with said dome, a valve communication between one of said pipes and said dome, a separate water-chamber at the base of

said outer water-chamber, direct-pipes connected with said last-named separate water-chamber, and a valve communication between said last-named separate water-chamber and said outer water-chamber.

700,746. MACHINE FOR HOLDING BRICKS OR BLOCKS.
CHARLES S. DAVEN, Boston Harbor, Mass. Filed Aug. 1, 1902. Serial No. 70,567. (No model.)

Claim.—1. In a machine of the kind described, the combination with a vertically-movable mold-box, of a laterally-movable plate adapted to be moved beneath the lower end of the mold-box, a horizontally-movable feed-box adapted to be moved across the upper end of the mold-box for the purpose of filling the said mold-box, the upwardly-movable plunger adapted to be projected through the plate and into the lower end of the mold-box, the downwardly-movable plunger adapted to be projected into the upper end of the mold-box, and means for operating the mold-box, plate, feed-box, lower and upper plungers, substantially as shown and described.

2. In a machine of the kind described, the combination with the mold-box movable vertically, of a plate having openings therein, the said plate being adapted to be moved horizontally beneath the mold-box, a downwardly-movable plunger and an upwardly-movable plunger, said upwardly-movable plunger being adapted to be projected through the plate into the lower portion of the mold-box, the upper end of said upwardly-movable plunger being tapered or beveled, together with means for moving the mold-box, plate and upper and lower plungers, substantially as shown and described.

3. In a machine of the kind described, the combination with the main frame having a bed-plate, of a plunger working upwardly through the said bed-plate, a plate slidably arranged upon the bed-plate, said plate having one or more openings through which the upwardly-movable plunger is adapted to project, a mold-box movable vertically and adapted to normally rest upon the plate, a downwardly-acting plunger, and means for operating the mold-box, plate, and the upper and lower plungers, substantially as shown and described.

4. In a machine of the kind described, the combination with the main frame having a bed-plate, the central portion of which has one or more openings produced therein, a plunger working upwardly through the said central portion, a plate having one or more apertures intermediate its ends and provided with a flange at one end, two or more of said plates being adapted to be arranged in series upon the bed-plate, the mold-box adapted to rest upon one of the die-plates, the downwardly-movable plunger, the sliding bar adapted to contact with one of the die-plates for the purpose of operating upon the series of die-plates, and means for moving the upper and lower plungers, mold-box, and sliding bar, substantially as shown and described.

5. In a machine of the kind described, the plate having one or more openings, said plate having a flange at one side, substantially as and for the purpose described.

6. In a machine of the kind described, the combination with the

main frame, of a mold-bar having castings connected to its opposite ends, said castings working in vertical guideways produced in the main frame, the ends of the said castings having strap-loops attached thereto, and provided with an anti-friction-bearing device, a rotary shaft having cams at its opposite ends adapted to operate in the strap-loops and upon the ends of the castings, whereby the mold-bar is raised and lowered, substantially as shown and described.

7. In a machine of the kind described, the combination with the main frame having a bed-plate formed with one or more openings, of a plunger adapted to be projected through the said openings, a sleeve to which the plunger is attached, and a rotary shaft arranged within the sleeve and carrying one or more cams adapted to operate upon the said sleeve whereby the plunger is raised or lowered, substantially as and for the purpose described.

8. In a machine of the kind described, the combination with the main frame having an apertured bed-plate, of a mold-bar having castings at one end working through guideways in the main frame and carrying strap-loops at their lower ends, and provided with anti-friction-bearing devices, the plates having openings adapted to correspond with the openings in the bed-plate, the plunger adapted to be projected through the bed-plate and plate and into the lower end of the mold-bar, the sleeve to which the plunger is attached, the rotary shaft having oppositely-disposed cams, one set of cams being adapted to raise and lower the mold-bar, the other set being adapted to raise and lower the plunger, and means for rotating the shaft carrying the cams, substantially as shown and described.

9. In a machine of the kind described, a series of mold-bars arranged side by side, plates interposed between the said bars, angular castings connected to the end bars, the lower ends of said angular castings carrying anti-friction-rollers and having strap-loops attached to the said ends, substantially as shown and described.

10. The combination with the main frame, having a bed-plate, of a vertically-movable mold-bar, a downwardly-acting plunger, two or more plates, one of which is adapted to rest beneath the mold-bar to receive the blocks or bricks, the slide-bar adapted to contact with the empty plate, said empty plate being adapted to engage the loaded plate, and means for operating the plunger, mold-bar, and sliding bar, substantially as shown and described.

700,747. GARNETT. BRASS DAVE, New York, N. Y. Filed Oct. 2, 1900. Serial No. 31,700. (No model.)

Claim.—1. A trousers having a yielding snugly-fitting waist portion, side openings interspersed therein and formed with inner and outer flaps open the front and rear portions of the trousers, flaps open the outer flaps adapted to engage suitable fastenings on the inner flaps, buckles secured to the opposite portions of the trousers from the outer flaps for holding them in proper position, and yielding means secured to the trousers at the rear of the waist portion, the structure being such that the buckles at the side will be capable of drawing up the yielding means at the sides and back of the trousers, substantially as described.

2. A yielding waist portion for trousers, comprising a waistband, side flaps interspersed therein, and yielding adjustable means for holding said flaps closed, a yielding strap at the rear of the trousers, made up of two elastic sections secured to the trousers and a double loop or buckle for

joining the ends of said sections, and an ordinary fly interspersed in the front of the waist and means at the side flaps for drawing up the yielding means at the sides of the trousers and at the rear of the trousers to make the same fit snugly though with a yielding pressure upon the wearer, substantially as described.

3. A garment having a waist-closure formed with openings at the sides, means for relieving the strain upon the wearer and yet holding the garment snugly around the wearer's waist, and means for preventing the same sagging at any point, substantially as described.

700,748. COMBINE MECHANICAL GARNER AND KESNTER. BRASS DAVE, New York, N. Y. Filed Oct. 2, 1900. Serial No. 31,700. (No model.)

Claim.—1. In a mechanical cipher, the cipher-receiving wheel consisting of paired plates having ledges formed thereon, and a stop-plate arranged between said ledged plates, substantially as set forth.

2. In a mechanical cipher, the cipher-receiving wheel consisting of paired plates having ledges formed thereon, and a recessed stop-plate arranged between said ledged plates, substantially as set forth.

3. In a mechanical cipher, the combination of a series of cipher-receiving wheels, notched controlling-wheels therefor, oscillating controlling-levers for said controlling-wheels and holding-pawls for said controlling-wheels having an oblique lip bridging the notches of the controlling-wheel, substantially as set forth.

4. In a mechanical cipher, the combination of an operating-shaft, a main operating handle or lever and a detachable connection between said handle or lever and shaft whereby the said handle or lever may be removed when desired to prevent malice or accidental interference with the machine.

5. In a mechanical cipher, the combination of an operating-shaft, a main handle or lever, an operating-eccentric and a ratchet-wheel and pawl connection between said handle and eccentric whereby the operative action of the handle is limited to a single direction.

6. In a mechanical cipher, the combination of cipher-wheels, oscillating controlling mechanism therefor provided with an oscillating shaft, a rotary handle, an operating-eccentric connected to said handle, a secondary lever and two ratchet connections therefrom to the eccentric and to the oscillating shaft to produce an oscillating movement of the latter by a rotary movement of the handle.

7. In a mechanical cipher, the combination of cipher-wheels and an operating-lever shaft, the said lever having strap-shaped portions embracing said shaft and arranged to act as spacers for the several wheels, substantially as set forth.

8. In a mechanical cipher, the combination of cipher-wheels, their shaft, a spring-arm on said shaft having the inclined portion as shown, an oscillating controlling-shaft, and an arm on said controlling-shaft having a portion adapted to engage said spring-arm, substantially as set forth.

9. In a machine of the character described, the combination of a main operating handle or lever, a locking device therefor, a series of cipher-

wheels, controlling device therefor comprising a set of inclined oscillating-levers, a purchase or numeral keyboard, selecting mechanism intermediate between the same and the controlling mechanism of the cipher-wheels, locking mechanism for said purchase or numeral keyboard, means controlled by the said cipher-wheel-controlling mechanism for unlatching said purchase or numeral keyboard and means controlled by the said purchase or numeral keyboard for unlatching said main handle or lever, substantially as set forth.

10. In a machine of the character described, the combination of the cipher-wheels, their controlling mechanism including oscillating controlling-levers, a purchase or numeral keyboard, selecting mechanism intermediate between said purchase or numeral keyboard and said controlling mechanism, a locking device for said keyboard for locking the keys in operated position and means controlled by the said controlling-levers for unlatching said locking device, substantially as set forth.

11. In a machine of the character described, the combination of a series of cipher-wheels, controlling mechanism therefor, a purchase or numeral keyboard comprising in addition to the numeral-keys special or department keys selecting mechanism intermediate between the said purchase or numeral keyboard and the said controlling mechanism, locking mechanism for said purchase or numeral keyboard, and means controlled by the said special or department keys for unlatching said mechanism, substantially as set forth.

12. In a machine of the character described, the combination of a series of cipher-wheels, controlling mechanism therefor comprising oscillating controlling-levers, a purchase or numeral keyboard comprising in addition to the purchase or numeral keys special or department keys, selecting mechanism intermediate between said purchase or numeral keyboard and said controlling mechanism, locking mechanism for said special or department keys, mechanism controlled by said special or department keys for unlatching said locking mechanism, locking mechanism for said special or department keys, and mechanism controlled by said controlling-levers for unlatching said department-key-locking mechanism, substantially as set forth.

13. In a machine of the character described, the combination of the cipher-wheels, controlling mechanism therefor comprising oscillating-levers, a purchase or numeral keyboard, selecting mechanism intermediate between said purchase or numeral keyboard and said controlling mechanism, a main operating handle or lever, the said purchase or numeral keyboard comprising in addition to the ordinary purchase or numeral keys special or department keys, locking mechanism for said purchase or numeral keys, mechanism controlled by said special or department keys for unlatching said locking mechanism, locking mechanism for said special or department keys, mechanism controlled by said controlling-levers for unlatching said department-key-locking mechanism, mechanism for locking said main handle or lever, and mechanism controlled by said purchase or numeral keys for unlatching said main handle or lever locking mechanism, substantially as set forth.

14. In a machine of the character described, the combination of a series of cipher-wheels, controlling and selecting mechanism therefor, said selecting mechanism including a permutation-shaft, a purchase or numeral keyboard having operative connection with said shaft, a main operating handle or lever, and locking mechanism therefor having operative connection with said permutation-shaft whereby the operation of the purchase or numeral keys will unlock said operating handle or lever, substantially as set forth.

15. In a machine of the character described, the combination of cipher-wheels, operating and locking mechanism therefor, said operating mechanism including a main handle or lever and mechanism intermediate between said main handle or lever and said locking mechanism whereby the said main handle or lever unlocks the said locking mechanism preliminary to operating the said cipher-wheels.

16. In a machine of the character described, the combination of cipher-wheels having operating and locking mechanism, the locking mechanism including a locking-pawl, a purchase or numeral keyboard, selecting mechanism controlled thereby and controlling the said cipher-wheels, and mechanism controlled by said selecting mechanism for causing the unlatching of the cipher-wheels by the operation of their operating mechanism.

17. In a machine of the character described, the combination of cipher-wheels, operating and locking mechanism therefor comprising a locking-pawl, and a lifting member therefor operated by the said operating mechanism, a purchase or numeral keyboard, and selecting mechanism controlled thereby and controlling the operation of said operating mechanism.

18. In a machine of the character described, the combination of a purchase or numeral keyboard, a series of tumblers or push-bars controlled thereby, a yoke adapted to engage and control the said bars to normal position, a main operating handle or lever and a restoring device controlled thereby for engaging said yoke, substantially as and for the purpose set forth.

19. In a machine of the character described, the combination of a purchase or numeral keyboard, a series of locking-plates therefor for holding any key depressed in its depressed position, a main operating handle or lever and means controlled thereby for operating all of said locking-plates simultaneously to release the keys in the initial movement of the handle, substantially as set forth.

20. In a machine of the character described, the combination of a purchase or numeral keyboard, a series of sliding locking-plates adapted to hold any key depressed in its depressed position, an operating-yoke therefor, an oscillating shaft controlling said operating-yoke, a restoring-bar adapted to operate said oscillating shaft, and a main handle or lever operating said restoring-bar, substantially as set forth.

21. In a machine of the character described, the combination of a purchase or numeral keyboard, a series of cipher-wheels, mechanism controlled by said purchase or numeral keyboard and controlling said cipher-wheels, a main handle or lever and mechanism operated by said handle or lever for unlatching said purchase or numeral keyboard and restoring the said controlling mechanism to normal position.

22. In a machine of the character described, the combination of a purchase or numeral keyboard, a series of cipher-wheels, selecting device therefor controlled by said purchase or numeral keyboard, and including permutation device, a main operating handle or lever, and mechanism controlled thereby for restoring said permutation device to normal position.

23. In a machine of the character described, the combination of a purchase or numeral keyboard, a series of cipher-wheels, selecting device therefor controlled by said purchase or numeral keyboard, and including special five-dollar-and-twenty-five-cent permutation device, a main operating handle or lever, and mechanism controlled thereby for restoring said special five-dollar-and-twenty-five-cent permutation device to normal position.

24. In a machine of the character described, the combination with the purchase or numeral keyboard, the tumblers or push-bars and the permutation device, of the main operating handle or lever, and a restoring-bar operated thereby and mechanism controlled by said restoring-bar for restoring to normal position the purchase or numeral keyboard, the tumblers or push-bars, and the permutation device.

25. In a machine of the character described, the combination with a purchase or numeral keyboard, push-bars or tumblers controlled thereby, special permutation device for said push-bars or tumblers including rotating toothed wheels, shafts carrying said wheels, spring retaining devices for holding said shafts in any predetermined position, a series of cipher-wheels and controlling device therefor, a main operating handle or lever, and mechanism intermediate between said controlling device and said permutation device and intermediate between said main handle or lever and said permutation device whereby said controlling device and said handle or lever alternately operate said permutation device.

26. In a machine of the character described, the combination of a purchase or numeral keyboard, a series of tumblers or push-bars controlled thereby, a series of auxiliary tumblers, certain of which hold the main tumblers or push-bars normally in elevated position, and means controlled by the said keyboard for shifting the said auxiliary tumblers to depress said normally-elevated push-bars or tumblers, substantially as set forth.

27. In a machine of the character described, the combination of a purchase or numeral keyboard, a series of push-bars or tumblers controlled thereby, a series of auxiliary tumblers, separate series of shafts or levers controlled by the several rows of keys in said keyboard, and mechanism substantially as described for connecting the two-rows of one row with one of the shafts of the next higher row of keys.

28. In a machine of the character described, the combination of a series of cipher-wheels, a series of controlling-wheels therefor, and their operating mechanism, a series of selecting device adapted to engage said operating mechanism, means for supporting said selecting mechanism on said operating device when so engaged, means for operating said selecting device and means for operating said controlling-wheels, substantially as set forth.

29. In a machine of the character described, the combination of a series of cipher-wheels or devices, two-part operating-shafts therefor arranged substantially at right angles, shaft-yokes in adjacent ends of the two parts of said shafts and mechanism controlled by said keyboard for causing the operation or engagement of said shafts, substantially as set forth.

30. In a combined mechanical cipher, the combination of a series of cipher-wheels, an indicator, a rotary main handle or lever, and oscillating mechanism for operating both said indicator and series of cipher-wheels, operatively connected with said main handle or lever, substantially as set forth.

31. In a machine of the character described, the combination of a purchase or numeral keyboard, indicator-wheel, shafts operating said wheels and having connection including shaft mechanism with said purchase or numeral keyboard, a locking-plate for the purchase or numeral

keys having operative connection with said clutch mechanism, substantially as set forth.

22. In a machine of the character described, the combination with the indicators and their operating-shafts, of clutch-pistons having teeth formed with parallel-sided bases and triangular outer ends, substantially as and for the purposes set forth.

23. In a machine of the character described, the combination of a purchase or numeral keyboard, the indicator-wheel, operating-shafts for said wheels, a locking-plate for the keys of said keyboard controlled by special or department keys of said keyboard and connecting mechanism between said locking-plate and indicator mechanism whereby the operation of said special or department keys unlocks the keyboard and sets the indicator mechanism in position for operation, substantially as set forth.

24. In a machine of the character described, the combination of a purchase or numeral keyboard, indicator-wheel, a series of shafts controlled by said keyboard, clutch mechanism for connecting and disconnecting the same from the indicator, a series of rack-bars connected to said shafts, a rotary shaft having arms adapted to successively engage said rack-bars and return them to normal position, a reciprocating bar or rod having ratchet-and-pawl connection with said rotary shaft and a rotary main handle or lever connected to and adapted to operate said reciprocating bar or rod.

25. In a machine of the character described, the combination of said wheels, indicator mechanism, recorder mechanism and means for controlling and operating the said several devices concurrently comprising a main operating-handle and controlling and purchase lever, substantially as set forth.

700,749. COW-MILKER. FRANK M. DUVEN, Thompson, Iowa, assignor to himself and Alva L. Hoover, Waterloo, Iowa. Filed Feb. 3, 1902. Serial No. 92,637. (No model.)

Claim.—1. In a cow-milker, the combination with a milk-receiver, an air-exhausting device, a collapsible tension-regulating chamber located intermediate said two elements, and tubular connections between the various elements; of tubes along the axial center of said chamber connected at their outer extremities with its ends and telescoping at their inner ends, the smaller tube being perforated within the chamber and the larger being perforated on its exterior, a plug-valve sliding within the larger tube, and means for pushing it normally inward so as to close the openings in this tube, the valve being pushed outward by the smaller tube when the chamber collapses.

2. In a cow-milker, the combination with a milk-receiver, an air-exhausting device, a collapsible tension-regulating chamber located intermediate said two elements, and tubular connections between the various elements; of a casing within which said chamber is located, springs connecting the ends of the casing with the ends of the chamber and tending to distend the latter, telescoping tubes within the chamber, the smaller being secured to one end and having perforations in its body and the larger passing through the other end and having perforations outside said chamber and its outer end closed, a sliding plug-valve within said larger tube adapted to be pushed outward by the smaller tube when the chamber is collapsed, and an expansive spring between said plug and the closed outer end of the larger tube.

700,750. PRINTING FURNITURE. EDWARD C. BOGHEMERT, St. Paul, Minn. Filed Jan. 21, 1902. Serial No. 92,638. (No model.)

Claim.—1. A border for printing, the base of which is provided with openings, and clamping-plugs mounted for sliding in said openings and extending in length the width of the sides thereof whereby they are adapted to extend beyond the opposite sides of the base.

2. A border for printing, the base of which is integral and rectangular, a plurality of the sides of said base being provided with openings, and clamping-plugs mounted and adapted to slide within the openings and of a length slightly exceeding the width of the base, whereby the plugs are adapted to extend beyond the opposite sides of the same.

3. A border for printing, the base of which is rectangular, said base

being provided at one side and end with an opening, and clamping-plugs mounted to loosely slide in said openings and of a length slightly exceeding the width of the base, whereby said plugs are adapted to project at opposite sides of the base.

4. A border for printing, the same comprising a base provided with circular openings and cylindrical clamping-plugs seated loosely and adapted to slide therein, said plugs exceeding in length the width of the base, whereby they are adapted to extend beyond the opposite sides thereof.

700,751. SAND-SIFTER. CLARENCE BERNHARDT, Newark, N. J. Filed Dec. 21, 1900. Serial No. 741,126. (No model.)

Claim.—1. In a sand-sifter having the frame with screen overlying at the side, an upwardly-projecting standpipe having a knocker pivoted thereon, and means for vibrating the knocker toward the periphery of the screen, the combination, with the stand of the knocker pivoted on the standpipe, of a knocker-arm jointed to each stand substantially in the plane of each pivot in such manner as to permit variations of the location of the blow delivered by the arm, substantially as herein set forth.

2. In a sand-sifter having the frame with bearings and shaft extending across the same with screens overlying at both ends and knockers actuated by the screens to beat their peripheries, the combination, with the shaft, of a clutch secured thereto, a pulley fitted loosely to the shaft, and means for engaging the pulley with the clutch whereby a continuously-running belt upon a single pulley operates the two screens at pleasure simultaneously.

3. In a sand-sifter, the combination, with a frame having bearings, and a shaft extending across the same and a screen overlying at the side of the frame, of a standpipe projected outwardly from the bearing with knocker-arm pivoted thereon to vibrate to and from the periphery of the screen, and the knocker-arm being adjustable laterally at various angles from its pivotal point, to vary the location of the blow upon the screen.

4. In a sand-sifter having the frame with bearings and shaft extending across the same with screens overlying at both ends and knockers actuated by the screens to beat their peripheries, the combination, with the shaft, of a clutch secured thereto and one of the bearings, and the opposite bearing having the clutch on its inner face, the lower pulley mounted between the bearings with hub adapted to engage each clutch, the spring on the pulley and clutch apart, and the double-curved

lever G having eye g in contact with the pulley and provided with beveled leg c to engage the clutch a on set forth, whereby the pulley can be engaged with the clutch by an operator at either side of the machine.

700,752. COVER-WRENCH. JAMES E. BRYAN, Milwaukee, Wis. Filed June 12, 1901. Serial No. 94,266. (No model.)

Claim.—A cover-wrench for fruit-jars, comprising two pivotally-connected clamping-levers, having grooved, outwardly diverging short arms provided with transverse apertures for the reception of the ends of the clamping-band; a circular clamping-band having its ends extending through, and elastically retained in, said apertures, and having intermediate portions thereof located by said grooves, whereby as said band is contracted around the cover, the surplus portion of the ends in their contracted position is free to pass through said apertures and the band is permitted to close in a circular position around the cover, while at the same time the outer ends of said diverging short arms are brought into contact with said clamping-band and the base of contact of said arms is increased, whereby the tendency of the cover to incline in either direction, as the cover is turned, is avoided, substantially as set forth.

700,753. BOX-PLATING DEVICE. FRANK E. PARKER, Brooklyn, N. Y. Filed Jan. 12, 1902. Serial No. 92,643. (No model.)

Claim.—1. A box-plate device comprising a body having one portion to open the plate vertically and a second portion to spread the plate transversely and lay it upon the body of the fabric.

2. A device for forming box-plate device comprising a body portion having one end to open the plate and having a rear portion or heel flattened or widened transversely and adapted to spread the plate laterally and lay it upon the body of the fabric.

3. A device for forming box-plate device comprising a body capable of being inserted into the plate and substantially filling the same transversely, and movable therethrough, said body having a flattened bottom or base-line and curved sides joining at the top to form a longitudinal central rib or edge adapted to fit the fold of the plate.

4. A device for forming box-plate device comprising a body capable of being inserted into the plate and substantially filling the same transversely, and adapted to be moved therethrough, said body having its opposite ends flattened, one in a plane at right angles to the other, one of said ends forming a wedge-shaped toe and the other a flattened heel.

5. A device for forming box-plate device comprising a body capable of being inserted into the plate and substantially filling the same transversely, and adapted to be moved therethrough, said body having its opposite ends flattened and disposed one at right angles to the other, to form a wedge-shaped front end, or toe, and a flattened rear end, or heel, said body having a flattened bottom and sides curvilinearly curved and joining each other along a longitudinal central line at the top or upper surface.

700,754. BOX-REVEALING BOTTLE. DANIEL F. FRIEDMAN, PAUL H. BRYAN, and HENRY KIMMEL, Walkerton, Ind.; and J. Edgar assignor of one-half of his right to William L. Wallace, Walkerton, Ind., and Ira J. Krichbaum, Tipton, Ind. Filed May 29, 1901. Serial No. 92,268. (No model.)

Claim.—A non-refillable bottle having a contracted neck for the reception of a valve, and an annular groove on the inner surface of the neck

above the contracted portion, in combination with a solid stopper having its periphery provided with a plurality of vertically-arranged tortuous passages, said passages substantially double V-shaped, an annular groove in the periphery of the stopper so arranged as to horizontally divide the tortuous passages thereby leaving one V-shaped passage above the groove and the other below it, a ball-spring within said groove, the ball-spring projecting beyond the periphery of the stopper and engaging with the groove in the bottle-neck.

700,755. TYPE-WRITER ATTACHMENT. JOHN S. PLAMMER, Bangor, Me. Filed Dec. 11, 1901. Serial No. 92,654. (No model.)

Claim.—A type-writer attachment comprising a foot-power adapted to be placed on the floor in any convenient position, composed of a base, an upright portion, side pieces and a stop, formed thereon, a triangular bracket and rectangular integral base, a spring, a flat-lever hinged to said base, a hooked, screw-threaded pin, operating in a screw-threaded recessed and headed bolt, in combination with a flexible metallic clamp, adapted to clamp a shift-key, and a flexible connection between said clamp and said pin, all substantially as described and for the purposes set forth.

700,756. NAIL-PULLER. EDWARD C. FOWLER, Fort Smith, Conn., assignor of one-half to William A. Starnes, Canton, Conn. Filed June 3, 1901. Serial No. 92,671. (No model.)

Claim.—1. In combination, the frame composed of two correspondingly-shaped parts, the fixed jaw pivoted between and to the two parts of the frame, the filling-piece pivoted between and to the two parts of the frame, the curved-headed movable jaw pivoted between and to the two parts of the frame, and the two pins projecting laterally from the two sides of the movable jaw, all substantially as described.

2. In combination, the frame composed of two correspondingly-shaped parts, the fixed jaw pivoted between and to the two parts of the frame, the filling-piece pivoted to and between the two parts of the frame, the curved-headed movable jaw pivoted between and to the two parts of the frame, and the two pins projecting laterally from both sides of the movable jaw, substantially as described.

700,757. NAIL-FULLER. EDWARD C. FOWLER, Fortville, Conn., assignor of one-half to William E. Blum, Canton, Conn. Filed Jan. 28, 1908. Serial No. 91,089. (No model.)

Claim.—1. In combination, the frame composed of two correspondingly-shaped parts having fulcrum extensions, the fixed jaw pivoted between and to the two parts of the frame, the filling-piece pivoted between and to the two parts of the frame, the curved-headed movable jaw pivoted between and to the two parts of the frame, and the handle having forked and embracing and riveted to the movable jaw and extended in a direction substantially the opposite of that of the fulcrum extension.

2. In combination, the frame composed of two correspondingly-shaped parts having fulcrum extensions, the fixed jaw pivoted between and to the two parts of the frame, the filling-piece pivoted to and between the two parts of the frame and carrying the bearing-piece, and the handle having forked and embracing and riveted to the movable jaw and extended in a direction substantially the opposite of that of the fulcrum extension.

3. In combination, the frame composed of two correspondingly-shaped parts having fulcrum extensions, the fixed jaw pivoted between and to the two parts of the frame, the filling-piece pivoted between and to the two parts of the frame, the curved-headed movable jaw pivoted between and to the two parts of the frame, the lateral projection of integral with the movable jaw, and the pin projecting from both sides of the movable jaw.

700,758. TARTLET-MACHINE. WILLIAM FRANK, Chicago, Ill. Filed Sept. 6, 1906. Serial No. 739,451. (No model.)

Claim.—1. The combination with the oscillating feeder, H, and the operating-lever, I, of the spring-pressed pin, i', guided in the lever and bearing upon the feeder to hold it in proper position; substantially as described.

2. The combination with the frame and driving-shaft, the die-table and the die, of the oscillating feeder upon the table, the lever, I, spring-pressed to bring the feeder over the die, the connections between the two ends of the operating-lever, I, and the driving-shaft for moving the feeder away from over the die and a movable stop adapted to be brought into the path of the lever to prevent the feeder from swinging over the die; substantially as described.

3. In a machine of the class described, the combination with a suitable frame, a die-table thereon, a driving-shaft journaled therein, upper and lower vertically-guided compressors supported thereby, a horizontally-oscillating feeder, a vertically-oscillating lever operated by the driving-shaft, actuated at its lower end and a curved flange upon the feeder adapted to engage the lever; substantially as described.

4. In a machine of the class described, the combination with a horizontally-oscillating feeder, of a pivot-pin therefor, having a circumferential groove and an eccentric locking-pin journaled in the frame adjacent to the pivot-pin, the eccentric portion of said locking-pin being adapted to oscillate into or out of the groove in the pivot-pin; substantially as described.

5. The combination with the table and die, of the pin, d, entering one table and bearing upon the die, the plate, e', carrying the pin at one end and having a shoulder bearing upon the table at the other and the screw, d', threaded in the table and clamping the plate, e', thereon; substantially as described.

6. The combination with the frame and driving-shaft, of the compressor-rod, U, guided therein, the head, c, upon the compressor-rod, the rod, c', guided in the frame to prevent the turning of the compressor-rod, the block, c'', eccentrically journaled upon the shaft and the piston, c''', secured in the block and having a ball-and-socket joint, with the head, c; substantially as described.

700,759. BUTTON. JOHN G. FREEDMAN, Berdonsville, N. J. Filed Aug. 20, 1908. Serial No. 24,612. (No model.)

Claim.—1. In a button, the combination with the head A; of the tubular shank B, provided with the annular flange B', in fixed relation with said head; the pin-plate C, in fixed relation with said shank; the flange C', upon said plate C, in longitudinal relation with said shank; two plates c, aligned upon the respective opposite extremities of said flange C'; the clamp-bar D, lying upon said plates c, and provided with the free edge d', opposed to the cavity in said shank in diametrical relation with said flange B'; substantially as set forth.

2. In a button, the combination with the head A; provided with the flange a; of the tubular shank B, having the flange B', fixed within said flange a; the circumferential shoulder B'', upon said shank; the pin-plate C, fixed upon said shank B, in contact with said shoulder B'; the annular flange B'', upon said shank opposed to said shoulder B'; and arranged to retain said plate C, in fixed relation with said shank B; the flange C', upon said plate C, in longitudinal relation with said shank B, and extending in a plane inclined with respect to the axis of said shank; two plates c, aligned upon said flange C', the clamp-bar D, provided with the free edge d', in opposition to said flange B'; and opposite legs d, on the respective extremities of said clamp-bar hingedly engaged with said plates, substantially as set forth.

700,760. WIND-WACKER. MICHAEL OLIVER, Oorobah, Ind. Filed Oct. 2, 1908. Serial No. 81,248. (No model.)

Claim.—In a wind-wacker, the combination with the inclined stack-tube comprising sections 2 and 3 one telescoping within the other, of rods 5 on opposite sides of said tube, a slidable yoke 4 on said rods and with which the rear ends of said rods are rigidly connected, said rods slidably supported in connection with both of said tubes, a yoke-frame 14 connecting the outer portions of said rods, a rod connecting the latter with a fixed frame portion in rear of the lower tube section, a head-frame connected with the outer end portions of said rods and a head connected therewith and means for imparting a sliding motion to said head-supporting rods, substantially as specified.

700,761. RAILWAY-TICKET. JOHN GOSWELL, Sandusky, Wis., assignor of one-half to Ralph P. Perry, Sandusky, Wis. Filed July 20, 1907. Serial No. 70,114. (No model.)

Claim.—1. A railway-ticket comprising a body having a destination-point indicated thereon, an opaque shield covering such indication, and a flange applied to the body over the shield, the body, shield and flange being weakened to present a detachable tongue bearing the destination indication.

2. A railway-ticket comprising a body having a destination-point indicated thereon, a staining-strip applied over such indication, and a flange applied to the body and covering the strip, the body, strip and flange being weakened to present a detachable tongue which carries the destination indication.

3. A ticket comprising a body having the destination for which it is issued indicated at an intermediate point, a strip of staining material applied over the destination indication, and a covering-strip applied over the face of the ticket and the staining-strip, the ticket-body, staining-strip and covering-strip being longitudinally perforated for a portion of the length of the said parts and the longitudinal perforations at one end being intersected by a line of transverse perforations to form a tongue which carries the destination indication.

4. A ticket having a tongue at an intermediate point therein normally covered by a staining-strip and a covering-strip, the tongue carrying the destination indication of the ticket, the tongue and the staining and covering strips being weakened so as to be separable along two edges and one end.

5. A railway-ticket comprising a body having a destination-point indicated thereon, a staining-strip applied over such indication, and a flange applied to the body and covering the strip and bearing printed matter such as the name of the road issuing the ticket, the body, strip and flange being weakened to present a detachable tongue which carries the destination indication.

700,762. VENTILATOR-FLUE. THOMAS J. GOSWELL, Lampasas, Tex. Filed July 20, 1901. Serial No. 60,232. (No model.)

Claim.—1. In a flue, an outer shell formed of separable sections capable of being united to form a flue and an inner shell composed of separable sections also capable of being united to form a flue of smaller diameter than said outer shell, the parts of each shell being adapted to be nested or packed one within the other.

2. In a flue, an outer shell of separable sections capable of being united to form a flue, an inner shell of separable sections capable of being united to form a flue of smaller diameter than said outer shell, and annular collars uniting said separable shells detachably, whereby said sections and collars may be separated and nested or packed, substantially as shown and described.

3. In a flue, an outer shell of separable sections capable of being united to form a flue, an inner shell of separable sections capable of being united to form a flue of smaller diameter than said outer shell, a central

separable rain-shield engaging and coupling-flue and extending over said main flue, and an extension-flue formed of separable sections and engaging said rain-shield and said coupling-section, substantially as shown and described.

4. In a flue, an outer shell of separable sections capable of being united to form a flue, an inner shell of separable sections capable of being united to form a flue of smaller diameter than said outer shell, a central separable rain-shield extending over said main flue and with its smaller end turned outward and engaging said coupling-section, and an extension-flue formed of separable sections and with the lower edge turned and engaging the outwardly-turned edge of said rain-shield, substantially as shown and described.

5. In a flue, a flue formed of separable sections capable of being united to form a flue and separated and nested and packed one within the other, and a rain-shield cap composed of separable sections and located above said flue, substantially as shown and described.

6. In a flue, a flue formed of separable sections capable of being united to form a flue and separated and nested and packed one within the other, and a rain-shield cap having clips adapted to be separably engaged by said flue-sections, substantially as shown and described.

700,768. TROLLEY-CATCHER. ALBERT W. HAN, Longmeadow, N. Y. Filed Oct. 26, 1901. Serial No. 73,626. (No model.)

Claim.—1. The combination of a reel, its winding-spring, a clutch, whereof one member is stationary, the other carried by the reel and loosely mounted thereon, in such manner that the inertia of the said reel-carried clutch member moves it into clutch with the stationary clutch member when the relative speed of the reel is suddenly increased.

2. The combination of a reel, its winding-spring, a clutch, whereof one member is stationary, the other carried by the reel and loosely mounted thereon, in such manner that the inertia of the said reel-carried clutch member moves it into clutch with the stationary clutch member when the relative speed of the reel is suddenly increased, and a yielding connection between the reel and the clutch member carried thereby.

3. In a trolley-catcher, the combination with a reel mounted on a fixed support, a winding-spring for the reel, a clutch, whereof one member is stationary and the other member is movably mounted on the reel and comprises a loosely-mounted clutch-actuator, the clutch-actuator a yielding connection between the said actuator and the reel, the several parts arranged so that the inertia of the clutch-actuator changes the relative positions of the actuator and reel when the relative speed of the reel is suddenly increased, and moves the clutch members together.

4. In a trolley-catcher, the combination with a reel, mounted on a fixed support, a winding-spring for the reel, a clutch, whereof one member is stationary, and the other member is movably mounted on the reel and comprises a clutch-actuator, the clutch-actuator, consisting of a piece loosely mounted concentrically with the reel, a yielding connection between the actuator and the reel, the several parts arranged so that the inertia of the clutch-actuator changes the relative positions of the actuator and the reel and moves the clutch members together when the relative speed of the reel is suddenly increased.

5. In a trolley-catcher, the combination with a reel mounted on a fixed support, a winding-spring for the reel, a clutch, whereof one member is stationary with and the other member is movably mounted on the reel and comprises a clutch-actuator, the clutch-actuator, consisting of a piece loosely mounted concentrically with the reel, a yielding connection between the actuator and the reel, the several parts arranged so that the inertia of the clutch-actuator changes the relative positions of the actuator and the reel and moves the clutch members together when the relative speed of the reel is suddenly increased.

6. The combination, in a trolley-catcher, of the reel, winding-spring, stationary support, reel thereon, part mounted on the reel and connected to an inertia-controlled part-actuator, the said part-actuator, consisting of a bar loosely mounted on a hub attached to and concentric with the reel, and a spring connecting the reel and actuator-bar, whereby the part is normally held clear of the reel, substantially as described.

7. The combination of a reel, its winding-spring, a clutch, whereof one member is stationary, the other carried by the reel, loosely mounted thereon, and balanced with respect to centrifugal force, in such manner that the inertia of the said reel-carried clutch member moves it into clutch with the stationary clutch member when the relative speed of the reel is suddenly increased.

8. The combination of a reel, its winding-spring, a clutch, whereof one member is stationary, the other carried by the reel, loosely mounted thereon, and balanced with respect to centrifugal force, in such manner that the inertia of the said reel-carried clutch member moves it into clutch with the stationary clutch member when the relative speed of the reel is suddenly increased, and a yielding connection between the reel and the clutch member carried thereby.

9. In a truck-catcher, the combination with a reel mounted on a fixed support, a winding-spring for the reel, a clutch, whereof one member is stationary, and the other member is movably mounted on the reel in balance with respect to centrifugal force, and comprises a loosely-mounted clutch-estimator, the clutch-estimator, a yielding connection between the said estimator and the reel, the several parts arranged so that the inertia of the clutch-estimator changes the relative positions of the estimator and reel when the relative speed of the reel is suddenly increased, and moves the clutch members together.

10. In a truck-catcher, the combination with a reel mounted on a fixed support, a winding-spring for the reel, a clutch, whereof one member is stationary and the other member is movably mounted on the reel and comprises a clutch-estimator, the clutch-estimator, consisting of a piece loosely mounted concentrically with the reel in balance with respect to centrifugal force, a yielding connection between the estimator and the reel, the several parts so arranged that the inertia of the clutch-estimator changes the relative positions of the estimator and the reel and moves the clutch members together when the relative speed of the reel is suddenly increased.

700,764. COVER FOR COOKING UTENSILS. HARRY E. BARRY, Wallerston, Ind. Filed July 1, 1891. Serial No. 68,712. (No model.)

Claim.—1. The combination with a cooking vessel and its lid, of a cover for the vessel provided with a ball-holder adapted to swing in a plane at right angles to the movement of the ball, said holder having a spring-clip to engage the ball and form a constructive engagement about the same.

2. In a device of the class described, a cover for cooking vessels provided with a ball-holder hinged to the cover at a point off of the center of the same, said holder formed from spring-wire bent into substantially U-shaped form, and provided with an inwardly-depending spring-clip adapted to engage the ball, said clip having a narrow neck, through which the ball is sprung.

3. In a device of the class described, a cover for cooking vessels provided with a ball-holder hinged to the cover at a point off of the center of the same, and adapted to swing in a plane at right angles to the ball of the vessel, said ball-holder having a resilient vane formed therein which engages the ball to form a constructive engagement about the same.

700,765. TRAIN SIGNALING APPARATUS. WILLIAM A. HARRIS and EDWARD S. E. HARRIS, Greenville, S. C. Filed Aug. 5, 1891. Serial No. 70,595. (No model.)

Claim.—1. In an apparatus substantially as described the combination of the casing, the whistle-valve piston having a port through which the pressure may pass to recharge the whistle-reservoir, and the whistle-valve, movable with respect to its piston and having a portion which is arranged to be adjusted to position to restrict the said port for the passage of pressure when the whistle-valve piston is moved downward substantially as set forth.

2. In an apparatus substantially as described, a whistle-valve having a piston and a valve proper operating therein and formed to provide a combined whistle-valve and release-valve arranged at one end to control the whistle-port and operating at its other end to restrict the passage of air in reestablishing the pressure in the whistle-reservoir when the brakes are put in release substantially as set forth.

3. In an apparatus substantially as described the combination of a casing, the whistle-reservoir communicating with the casing, the whistle-valve having a piston operating in the casing above the connection of the whistle-reservoir and provided with a port for the passage of pressure to said reservoir and with a tubular stem, and the valve proper operating in said tubular stem and arranged at one end to restrict the whistle-port and at its other end to control the port in the whistle-piston when the brakes are put in release substantially as set forth.

4. In an apparatus substantially as described the whistle-valve piston having a port for the passage of pressure and the whistle-valve proper arranged at one end to operate upon said port and having at each end means whereby to permit a restricted flow of pressure through the port when the valve proper is closed to said port substantially as set forth.

5. In an apparatus substantially as described the combination of the casing having the whistle-port, the whistle-valve having a piston provided with a port, and a valve proper movable with relation to the piston, arranged at one end to control the whistle-port and at its other end to operate upon the port in the piston and made of such length as to fit snugly between the whistle-port and the whistle-valve piston when the latter is adjusted to its lowermost position substantially as set forth.

6. The combination of the casing having a cylinder for the whistle-valve piston, the whistle-valve piston having a valve-surface within its rim co-operating with a seat in the casing, and provided with a control port for the passage of pressure to the whistle-reservoir, the casing being provided with means for venting the air from the space indicated by the cut-off portion of the piston, and the whistle-valve proper arranged at one end to control the whistle-port and at its other end to control the port in the piston substantially as set forth.

7. In an apparatus substantially as described the combination of the casing having means for connection with the whistle-valve reservoir and with the train-line, the whistle-valve piston having a port for the passage of pressure from the train-line to the whistle-reservoir and a valve connected with said piston and arranged to restrict such passage of pressure when the brakes are put in release substantially as set forth.

8. In an apparatus substantially as described the combination of the casing, the whistle-valve piston having a port for the passage of pressure to the whistle-valve reservoir, and the whistle-valve proper having a portion by which to control said port, and the main piston arranged to control the whistle-valve in all operations of the brakes substantially as set forth.

9. In an apparatus substantially as described the combination of the casing, the whistle-piston, the main piston made of greater area than the whistle-piston and means whereby the main piston will be caused to travel down and control the whistle-piston in all operations of the brakes substantially as set forth.

10. In an apparatus substantially as described the combination of the casing, the whistle-valve piston, the main piston arranged to control the whistle-valve piston, the equalizing-reservoir, and the whistle-valve reservoir, passages being provided whereby the pressure in the equalizing-reservoir will operate on the side of the main piston next to the whistle-valve while the pressure from the whistle-reservoir will operate on the opposite side of said main piston whereby the main piston will be caused

to travel toward the whistle-valve in all operations of the brakes substantially as set forth.

11. In an apparatus substantially as described the combination of the casing having means for connection with the whistle-reservoir and with the train-line, the whistle-valve, means whereby the whistle-valve may be opened to permit the venting of the whistle by pressure from the whistle-reservoir, and a device operated by the pressure from the whistle-reservoir whereby to hold the whistle-valve closed by such pressure when the parts are operated except for venting the whistle and refilling the whistle-reservoir after brakes are put in release, whereby the pressure in the whistle-reservoir may be used at one time to vent the whistle and at another time to prevent any venting of the whistle substantially as set forth.

12. In an apparatus substantially as described, the combination of the casing, the main valve, the whistle-valve, and connection whereby pressure may operate in all applications of the brakes to move the main valve toward the whistle-valve, substantially as set forth.

13. In an apparatus substantially as described, the combination of the casing, the main valve, the whistle-valve, connection whereby pressure from the whistle-reservoir may operate on the side of the main piston opposite the whistle-valve, the said main piston being arranged to move downward in all applications of the brakes and to hold the whistle-valve to its seat and to open up the passage for the pressure to the main line when so moved down substantially as set forth.

14. In an apparatus substantially as described, the combination of the casing, the whistle valve and piston and the main piston, constructed when moved downward from its normal position to open the passage for the pressure from the whistle-reservoir to the main line, substantially as set forth.

15. In an apparatus substantially as described, the combination of the casing, the whistle-valve, the main piston, by which to control the whistle-valve in all applications of the brakes, and means for limiting the upward movement of the main piston beyond its normal position, said main piston being provided with a passage for the pressure, which passage will be opened when the main piston is depressed below its normal position, substantially as set forth.

16. In an apparatus substantially as described, the combination of the casing, the whistle piston and valve, the main piston arranged to move downward and control the whistle-valve in all operations of the brakes, and means for preventing the upward movement of the main piston above its normal position, substantially as set forth.

17. In an apparatus substantially as described, the combination of the casing, the whistle-reservoir, the whistle-valve, the main valve, the equalizing-reservoir, and connection whereby pressure from the equalizing-reservoir will operate below the main piston and pressure from the whistle-reservoir will operate above the main piston, substantially as set forth.

18. In an apparatus substantially as described, the combination of the casing, the whistle-valve, the main piston arranged to control the whistle-valve, the emergency-valve, opening toward the train-line, the equalizing-reservoir and connection whereby the emergency-valve will be opened by the equalizing-reservoir pressure, substantially as set forth.

19. In an apparatus substantially as described, the combination of the casing, having means for connection with the train-line, the equalizing-reservoir and the whistle-reservoir, the whistle-valve, the main piston, means for admitting the pressure from the equalizing-reservoir below the main piston, the emergency-valve controlling the passage of pressure from below the main piston to the main line, and means for admitting pressure from the whistle-reservoir above the main piston, substantially as set forth.

20. In an apparatus substantially as described, the combination of the casing having cylinders for the main piston and for the whistle-valve piston and means for connection with the train-line, the equalizing-reservoir and the whistle-reservoir, the main piston arranged to control the whistle-valve piston in the application of the brakes, the whistle-valve piston having a portion for the passage of pressure, and the whistle-valve proper movable with respect to its piston and having a portion which may be adjusted to position to restrict the passage of pressure through the port in the whistle-valve piston substantially as set forth.

21. In an apparatus substantially as described, the combination of the casing, the whistle-valve piston having a port for the passage of pressure through it and the whistle-valve proper arranged at one end to control the whistle-port and at its other end to control the port in the piston and having said and grooved for the gradual passage of pressure past it when adjusted into contact with the port substantially as set forth.

22. In an apparatus substantially as described, the combination of the casing having means for connection with the whistle-reservoir and the train-line, the whistle-valve having a piston, the main piston arranged to control the whistle-valve, and means whereby pressure from the whistle-reservoir may be admitted below the whistle-valve piston and above the main piston, substantially as set forth.

23. The combination, in an apparatus substantially as described, of the casing, the whistle-valve having a piston provided with a port for the passage of pressure, and a valve proper arranged at one end to control the whistle-port and at its other end to control the port for the passage of pressure, and the main piston having a tubular stem arranged to bear upon the valve-piston and actuated for the passage of pressure, and provided within the said stem with a valve arranged to control the port in the whistle-valve piston, substantially as set forth.

24. A signal apparatus substantially as described having a whistle-valve, a main piston having a tubular stem and a valve operating therein, and provided within said stem with a passage or passages through which pressure may operate from the whistle-reservoir to the main line in the applications of the brakes, substantially as set forth.

25. In an apparatus substantially as described, the combination of the casing having means for connection with the train-line, the equalizing-reservoir, and the whistle-reservoir, and provided with cylinders for the main piston and the whistle-valve piston, and having ports or passages for the pressure from the whistle-reservoir below the whistle-valve piston and above the main piston and for the passage of pressure from the equalizing-reservoir below the main piston, and from the train-line to a point above the whistle-valve piston, and also a passage for the pressure below the main piston to the train-line, the emergency-valve for controlling the latter passage, the main piston having the tubular stem and the valve operating therein, and the whistle-valve having a piston and the valve proper, all substantially as set forth for the purposes set forth.

26. In an apparatus substantially as described, the combination of the casing, the whistle-valve and its piston having a port for the passage of pressure, the main piston having a tubular stem and a valve operating therein, and having within said tubular stem a passage for the pressure and at the lower end of the stem means for the exit of such pressure to the main-line, and connection for the passage of pressure from the whistle-reservoir to a point above the main piston and below the whistle-piston, all substantially as described, whereby pressure may pass from the train-line through the whistle-valve piston to the whistle-reservoir in recharging the latter, and may pass from the whistle-reservoir through the tubular stem of the main piston in equalizing pressure in the train-line and whistle-reservoir in the application of the brakes, substantially as set forth.

27. In an apparatus substantially as described, the combination of the casing having a cylinder for the whistle-valve piston and a cylinder for the main piston, and having an emergency port or passage leading from the lower portion of the latter cylinder to communicate with the train-line, the emergency-valve controlling said port and opening toward the train-line, the whistle-valve and its piston, the main piston, the whistle-valve reservoir, the equalizing-reservoir, a connection whereby the pressure in the equalizing-reservoir may pass to operate below the main piston, and a connection whereby the pressure in the whistle-reservoir may operate above the main piston, substantially as set forth.

28. The combination of the casing having a cylinder for the main piston and an emergency-passage leading from the lower end of said cylinder to the train-line, and a controlled port or passage leading to the lower portion of said cylinder from the equalizing-reservoir, whereby in the emergency application, the pressure may pass from below the main piston to the train-line, more rapidly than it can be applied through the said controlled passage, the main piston, the whistle-valve, and means whereby pressure may pass from the whistle-reservoir to a point above the main piston, substantially as set forth.

29. In an apparatus substantially as described the combination of the casing the whistle-valve piston having a port for the passage of pressure and a whistle-valve proper having a portion arranged to restrict said port in the application of the brakes, the main piston, and connection whereby pressure from the whistle-reservoir may be admitted to operate above said main piston substantially as set forth.

30. The combination in an apparatus substantially as described of the casing, the whistle-reservoir, the whistle-valve and its piston, the main piston arranged to move toward the whistle-valve in all applications of the brakes, and connection whereby pressure from the whistle-reservoir may be admitted above the main piston whereby to effect such downward movement thereof substantially as set forth.

700,766. TRAIN SIGNALING APPARATUS. WILLIAM A. HARRIS and EDWARD S. E. HARRIS, Greenville, S. C. Filed Aug. 5, 1891. Serial No. 70,596. (No model.)

Claim.—1. In an apparatus substantially as described, the combination of the casing, the whistle-valve, an intercepting-valve by which to prevent the passage of pressure to the whistle, and means by which the said intercepting-valve may be automatically operated by pressure independently of that controlled by the whistle-valve.

2. The combination of the casing, the whistle-valve, and an inter-

capturing device arranged beyond the whistle-valve and adapted to prevent the passage of pressure to the whistle when the whistle-valve is open in certain operations, and means by which the said intercepting-valve may be operated by the exhaust from the engineer's brake-valve.

3. The combination of the casing, the whistle-valve, and an intercepting-valve arranged to prevent the passage of pressure to the whistle when the whistle-valve is open in certain operations, said intercepting-valve being provided with a passage for the pressure from the whistle-valve reservoir when the said intercepting-valve is adjusted to intercepting position and with means for operation by such pressure.

4. The combination of the casing having a cylinder for the piston of the intercepting-valve, the whistle-valve, the intercepting-valve and means whereby the intercepting-valve may be operated by the exhaust from the engineer's brake-valve.

5. The combination with the casing having a cylinder for the piston of the intercepting-valve, whistle-part D and a valve-seat F and provided with a passage E, and the intercepting-valve arranged for operation by the exhaust-pressure from the engineer's brake-valve and having a piston engaging in the cylinder of the casing, and a tubular stem operating in the chamber E and provided with a valve portion to fit the seat F and a port communicating with its bore and arranged for registration with the whistle-part D.

6. In an apparatus substantially as described, the combination of the casing having a cylinder for the piston of the intercepting-valve and an opening G leading to said cylinder, the whistle-valve, the intercepting-valve having a piston operating in the cylinder of the casing and provided with a portion by which to shut off the passage of pressure to the whistle and also provided at its outer end with a plug-valve to close the opening G leading to the cylinder for the said intercepting-valve piston.

7. In an apparatus substantially as described, the combination with the casing, the whistle-valve and connections whereby said whistle-valve will be caused to move upward in the service and emergency applications of the brakes by the engineer's brake-valve, and means operated by the exhaust-pressure from the engineer's brake-valve whereby to prevent the passage of pressure to the whistle in the said service and emergency applications of the brakes.

8. An apparatus substantially as described, comprising the casing, the whistle-valve, the engineer's brake-valve, and means operated by the exhaust-pressure from the engineer's brake-valve by which to prevent the sounding of the whistle in the service and emergency applications of the brakes by the operation of the engineer's brake-valve.

9. The combination in an apparatus substantially as described, of the casing, the whistle-valve, the engineer's brake-valve, connections whereby the whistle-valve will be opened in the service and emergency applications of the brakes by the engineer's brake-valve, and a device operated by the exhaust-pressure from the engineer's brake-valve and arranged to shut off the passage of pressure to the whistle when the whistle-valve is open in the service and emergency applications of the brakes by the engineer's brake-valve.

10. The combination of the engineer's brake-valve, and the train-line, of the signal having a casing, a connection between said signal and the train-line for the passage of train-line pressure between the train-line and signal, the whistle-valve, the intercepting device by which to prevent the passage of pressure to the whistle in the service and emergency applications of the brakes by the operation of the engineer's brake-valve and connections whereby the exhaust from the engineer's valve in such applications will operate the intercepting device to position to shut off the passage of pressure to the whistle.

11. The combination of the engineer's brake-valve, the signal apparatus including a whistle-valve, and an intercepting device arranged to shut off the passage of pressure to the whistle when the whistle-valve is opened in certain operations of the apparatus, and means whereby the intercepting device will be operated by the exhaust-pressure from the engineer's brake-valve in the service and emergency applications of the brakes, said means being disconnected or free of any direct connection with the exhaust-ports of the engineer's brake-valve whereby the said exhaust-pressure will operate the intercepting device and yet may be discharged freely into atmosphere etc.

12. An apparatus substantially as described, having the whistle-valve and provided with means operated by the exhaust-pressure from the engineer's valve in the emergency and service applications of the brakes whereby to prevent the passage of pressure to the whistle.

13. A signal apparatus comprising the casing, means connecting said casing with the train-line whereby it may be influenced by variations in pressure in said line, and controlling device for the whistle including an intercepting device arranged for operation by the exhaust from the engineer's brake-valve and adapted when so operated to prevent the passage of pressure to the whistle.

14. The combination with the signal-casing and the whistle-valve, of the intercepting-valve arranged for initial operation by the exhaust-pressure from the engineer's brake-valve, and means whereby the said intercepting-valve may be held by the whistle-reservoir pressure in the position to which it is adjusted by the said exhaust-pressure.

15. The combination of the signal-casing, the whistle-valve, the intercepting-valve arranged to control the whistle-part and provided with a valve portion to shut off the passage of pressure to the whistle and the passage for the pressure from the whistle-reservoir, said intercepting-valve being also provided with a piston for operation by the exhaust from the engineer's brake-valve and with a valve portion for shutting off the passage of the exhaust-pressure to said piston after the initial movement of the intercepting-valve.

16. The signal apparatus comprising the casing, the whistle-valve arranged to be adjusted to open position in all operations of the brakes and in all signaling operations, and an intercepting device arranged between the whistle-valve and the whistle and adapted for operation, in the emergency and service applications of the brakes by the engineer's brake-valve, to position to shut off the passage of pressure to the whistle.

17. A signal device provided with means arranged for operation by the exhaust from the engineer's brake-valve, in the service and emergency applications of the brakes whereby to intercept the air passing from the signal-valve to the signal and to prevent the operation of the signal by any operation of the engineer's brake-valve in the application of the brakes.

18. The combination with the engineer's brake-valve and a signal apparatus, of a pipe or pipes leading from said signal and opening adjacent to the exhaust port or ports of the engineer's brake-valve whereby the exhaust-pressure discharging from said port will operate upon the air in said pipe, and device in the signal apparatus arranged for operation by such exhaust-pressure.

19. A signal apparatus provided with means for operation by the exhaust-pressure from the engineer's brake-valve combined with the engineer's brake-valve having the exhaust ports and pipes connected with the signal and opening opposite the exhaust-ports of the engineer's brake-valve and spaced apart from said ports whereby the gust of air exhausted from said ports will operate the device in the signal and there will be no choking of the exhaust.

20. The combination of the engineer's brake-valve, the train-line, the signal having a casing, a whistle-valve and an intercepting-valve operating between the whistle-valve and the whistle, connection between the casing and the train-line whereby the whistle-valve will move upward in all applications of the brakes, and connections whereby the intercepting-valve will be operated by the exhaust-pressure from the engineer's valve.

700,767. HETALLEN CAR. HARRY S. HARR, Chicago, Ill., assignor to the Hopper Patent Car Company, Chicago, Ill., a Corporation of Illinois. Filed July 2, 1899. Serial No. 722,284. (No model.)

Claim.—1. In a car of the class described, the combination of an open unobstructed body-supporting frame, composed of transverse

beams at or near the ends, and side plate-girders rigidly connected to and resting on the top of said beams, substantially as described.

2. In a car of the class described, the combination with a body, of supporting-frame composed of transverse beams at or near the ends of the body, and side plate-girders connected rigidly to and resting on the top of said beams, said body being entirely supported from said beams and side girders, substantially as described.

3. In a car of the class described, the combination of a combined end sill and body-bolster arranged transversely of the car at or near each end thereof, side plate-girders supported at or near their ends by and rigidly connected to the top of the combined end sill and bolster, and a bottom portion supported by the side girders, substantially as described.

4. In a car of the class described, the combination of a combined end sill and body-bolster arranged transversely of and at or near each end of the car, a hopper portion, side plate-girders supported at their ends upon the combined sill and bolster and supporting the hopper, and intermediate longitudinal plate-girders supported at their ends upon the combined sill and bolster to assist in supporting the hopper, substantially as described.

5. In a car of the class described, the combination of a combined end sill and body-bolster arranged transversely of and at or near each end of the car, a hopper portion and two beam-girders supported at their ends upon the combined sill and bolster and formed of two side plate-girders, two intermediate plate-girders, means for securing them—the side and intermediate girders—together at or near their lower portions and supporting the hopper and a portion of the sloping side or bottom of the hopper, substantially as described.

6. In a car of the class described, the combination of a car-floor or bottom portion, side plate-girders supporting the same, a combined end sill and body-bolster arranged transversely of the car in position to be supported by the truck and secured to and below the ends of the side plate-girders to support the same and transmit the loading strains to said girders, and means for transversely loading the bolster, substantially as described.

7. In a car of the class described, the combination of a car-floor or bottom portion, two side plate-girders supporting the same, a combined end sill and body-bolster arranged transversely of and secured to and below the ends of the side plate-girders to support the same and transmit the loading strains to said girders, and a longitudinal strap member secured to each end of said combined end sill and bolster to assist them in carrying the loads, substantially as described.

8. In a car of the class described, the combination of a car-floor or bottom portion, two side plate-girders supporting the same, a combined

end sill and body-bolster arranged transversely of and secured to the ends of the side plate-girders to support the weight thereof and transmit the loading strains to said girders, draft-rigging-supporting members secured to and extending out and down from the combined sill and bolster, and means for securing said draft members in loading strains and vertical strains, substantially as described.

9. In a car of the class described, the combination with a body portion of supporting side plate-girders, having their upper edges bent to fit the adjacent portions of the body, and connecting members at the ends between the girders.

10. In a car of the class described, a combined end sill and body-bolster formed of two longitudinal members separated at their central portion and brought together at their ends, a spiral plate secured between the longitudinal members at each end and extending upwardly therefrom, a transverse member with its ends secured to the vertical plates, and a strut between the transverse and longitudinal members, substantially as described.

11. In a car of the class described, a combined end sill and body-bolster formed of metal plates vertically disposed and extending longitudinally thereof, angle-irons secured to the upper and lower edges of the same with their flanges extending outwardly therefrom and from the center in a horizontal plane, the longitudinal vertically-disposed members being separate at their transverse center and their flat vertical portions being bent toward each other and secured together at their ends, substantially as described.

12. In a car of the class described, two side plate-girders, one on each side, for supporting the body of the car longitudinally, each girder having a single plate-body and an independent flanged rail on each side at the bottom forming a self-contained side girder, substantially as described.

13. In a car-body-supporting frame, the combination of a side girder for each side formed of an outer girder having a metal plate-body and separate flanged metal rails united in the metal plate-body at the top and bottom edges thereof and an intermediate stop-girder having a metal plate-body and separate flanged metal rails united in the bottom edges thereof, and a cross-support at each end forming an end sill and body-bolster consisting of a metal plate-body and separate flanged metal rails united to the metal plate-body at the top and bottom edges on the outer face thereof, substantially as described.

14. In a car of the class described, the combination of a portion acting as an end sill and body-bolster, consisting of a cross-support formed by metal plates and independent top and bottom flanged rails on the outer face of the plates and located transversely of the car at each end, two side plate-girders, each consisting of a single metal plate-body, a flanged independent rail on each side of the metal plate-body at the bottom and a flanged independent metal rail on the outer face of the plate-body at the top, each girder supported at its ends only by the combined end sill and body-bolster, and a hopper-shaped car-body seated by the side girders, substantially as described.

15. In a car of the class described, the combination of a combined end sill and body-bolster consisting of a cross-support formed of metal plates, each plate having at the top and bottom on its outer face an independent flanged rail riveted thereto and located transversely of the car at or near each end, a hopper-shaped car-body having its sides and ends inclined, two side plate-girders supported at their ends by the combined end sill and body-bolster, each girder consisting of a single metal plate-body, an independent flanged rail at the bottom of the plate-body on each side and riveted thereto, an independent flanged rail at the top of the plate-body and riveted thereto forming a self-contained plate-girder on each side of the car supporting the hopper-shaped car-body, and intermediate stop-girders, each consisting of a single metal plate-body and an independent flanged rail on each side at the bottom riveted to the plate-body, supported at the ends by end sill and body-bolster, and furnishing a support for the hopper-shaped car-body against outward sagging or bending, substantially as described.

16. In a car of the class described, the combination of a combined end sill and body-bolster arranged transversely of and at or near each end of the car and consisting of metal plates, each plate having at the top and bottom on the outer face an independent flanged metal rail riveted thereto, a hopper-shaped car-body having inward-sloping sides and ends and two beam-girders supported at their ends upon the combined end sill and body-bolster and formed of two side plate-girders and two intermediate plate-girders, each side plate-girder consisting of a single metal body and an independent flanged metal rail on each side at the bottom and an independent flanged metal rail at the top of the plate-body and riveted thereto, and each stop-girder consisting of a single metal plate-body and an independent flanged metal rail on each side of the metal plate-body at the bottom and riveted thereto, and means for securing the side plate-girders and stop-girders together to the other at the bottom, for the beam-girders to support the hopper floor or bottom, substantially as described.

17. In a car of the class described, the combination of a car-floor or bottom portion, two side plate-girders supporting the same, a combined end sill and body-bolster arranged transversely of and secured to and below the ends of the side plate-girders to support the same and transmit the loading strains to said girders, and a longitudinal strap member secured to each end of said combined end sill and bolster to assist them in carrying the loads, substantially as described.

18. In a car of the class described, the combination of a car-floor or bottom portion, two side plate-girders supporting the same, a combined

17. In a car of the class described, the combination of a car-body, two side plate-girders supporting the car-body, each consisting of a single metal plate-body and an independent flanged metal rail at the bottom of the metal plate-body on each side and riveted thereto and an independent flanged metal rail at the top of the metal plate-body on the outer face and riveted thereto, and a combined end sill and body-bolster arranged transversely of and secured to the ends of the side plate-girders for supporting the girders and transmitting buffing strains thereto, substantially as described.

18. In a car of the class described, the combination of a car-body, two side plate-girders supporting the car-body, each consisting of a single metal plate-body and an independent flanged metal rail at the bottom of the metal plate-body on each side and riveted thereto and an independent flanged metal rail at the top of the metal body on the outer face thereof and riveted thereto, a combined end sill and body-bolster arranged transversely of and secured to the ends of the side plate-girders and furnishing a support for the girders and transmitting buffing strains thereto, and a draft-bumper at each end of the car projecting from the combined end sill and body-bolster and extending the combined end sill and bolster in carrying the load, substantially as described.

19. In a car of the class described, the combination of a car-body, two side plate-girders supporting the body, each consisting of a single metal plate-body and independent flanged metal rails at the top and bottom of the plate-body and riveted thereto for each girder to have a rail at its top and a rail on each side at the bottom to be self-contained and support the weight of the body and load, a combined end sill and body-bolster arranged transversely of and secured to the ends of the side plate-girders supporting the girders at the ends and transmitting buffing strains to the girders, a draft-bumper at each end of the car projecting outward from the combined end sill and bolster, and means for securing each draft-bumper in resisting sidewise and vertical strains, substantially as described.

20. In a metal car, the combination with side plate-girders, of body-bolsters to which the side girders are secured, a car-body rigidly held between the side girders, reinforcing-standard secured to the side girders and upper edge of the body, and independent connecting-braces between the bolster and body and the side plate-girders and body, substantially as described.

21. The combination with side plate-girders, of end sills rigidly connecting the ends of the girders, a body supported between the girders and braces extending from the upper and lower portions of the end sills to the end of the body, substantially as described.

22. The combination with a side supporting-plate, of an obliquely-arranged hopper-plate riveted thereto at a point above the lower edge of the side plate, and a bracing member inside of said side supporting-plate and having a portion adapted to brace the hopper-plate, substantially as described.

23. The combination with a side supporting-plate, of an obliquely-arranged hopper-plate riveted thereto at a point above the lower edge of the side plate, and a bracing member inside of said side supporting-plate and having a portion adapted to brace the hopper-plate, an angle-bar secured to the lower edge of the side plate, and vertical posts secured to the side plate, substantially as described.

24. The combination with side girders, of an end sill, corner-posts supported directly by said end sill and secured to said side girders, and a car-body whose sides are supported by said side girders and whose ends are supported by said corner-posts, substantially as described.

25. The combination with a metal car-body, of side girders, an end sill connected directly to said side girders, angle corner-posts secured to said girders and supported by said end sill, and where upper ends are connected to said car-body, substantially as described.

26. In a car of the class described the combination with a body, of a bolster or end sill, draft-rigging members and the plates P and P' extending from the end members to the body.

27. In a car of the class described, the combination with a body, of a bolster, a draft-rigging member, the brace-plates, P, P', and the horizontal plates P', P'.

28. The combination with a car-body having an overhanging end, of a transverse bolster, corner-posts connected to said bolster and to said overhanging end, a structure supported by said bolster and extending forwardly, and braces for the central portion of said inclined end supported by said forwardly-extending structure and connected to the overhanging end of the car-body, substantially as described.

29. In a car, the combination with side plate-girders, and body-bolsters supporting said plate-girders, of an inclined bottom and supports for said inclined bottom springing from and rigidly secured to said bolsters, substantially as described.

30. In a car of the class described, the combination of a combined end sill and body-bolster arranged transversely of and at or near each end of the car, a hopper portion, and side plate-girders supported by said combined end sill and bolsters at each side of the hopper portion and con-

nected to form in effect one girder, said hopper portion being supported by said side plate-girders, substantially as described.

31. In a hopper-bottom car, a draft-beam extending forwardly from the bolster, the outer end of the draft-beam depending on the overhanging part of the car-body for its vertical support, substantially as described.

32. In a hopper-bottom car, a body-bolster composed of an upper and a lower part, the lower part being bolted down, and also being riveted to the end of the draft-beam, substantially as described.

33. In a car, the combination with a car-body having an overhanging front part, of a bolster, a draft member extending forward from said bolster, and a connection from said draft member to the overhanging part of said car-body for supporting said draft member, substantially as described.

34. In a metal car, the combination with a car-body, of side body-girders extending longitudinally and comprising in their construction plate-girders, a portion of the walls of the car-body, and transverse connections, substantially as described.

35. In a metal car, the combination with a car-body, of side body-girders extending longitudinally and each comprising in its structure a plurality of plate-girders, a portion of the walls of the car-body, and transverse connections, substantially as described.

36. In a car of the class described the combination with the body, of supporting means therefor, a sill or bolster, a cross-piece such as C' on the body and a brace between the cross-piece and the bolster.

37. In a hopper-bottom car, a draft-beam extending outward from the bolster the outer portion of the draft-beam depending on an overhanging part of the car-body for its vertical support.

38. In a hopper-bottom car a draft-beam extending forward from the bolster and a connection between the draft-beam and an overhanging portion of the car-body whereby the draft-beam is supported in its position by the said overhanging portion of the car-body.

700,768. GILLES SYSTEM FOR MOTOR-VEHICLES. WILLIAM A. HANSEN AND JAMES W. FARRAR, WRITERS, CHICAGO, ILL.; said Hansen assignor to said Farrar. Filed June 25, 1902. Serial No. 21,642. (No model.)

Claim.—1. In a motor-vehicle provided with a hydrocarbon-motor, the combination of a relief-valve for the motor-cylinder, a lubricating-oil valve, a connection between said valves whereby the one may be closed when the other is open, and means for operating said valves.

2. In a motor-vehicle provided with a hydrocarbon-motor, the combination of a cylinder relief-valve, a cylinder-oiling valve, a connection between said valves whereby one may be closed when the other is open and vice versa, and means for operating the valves.

3. In a motor-vehicle provided with a hydrocarbon-motor, the combination of a cylinder relief-valve, a series of lubricating-oil valves, and connections for simultaneously operating all of said valves, said connections being arranged to simultaneously open the relief-valve and close the oil-valves or, vice versa, to close the relief-valve and open the oil-valves.

4. In a motor-vehicle provided with a hydrocarbon-motor, an oil-tank provided with a series of oil-outlets, a common valve for all of said outlets, a cylinder relief-valve, and connections between the relief-valve and the said oil-valve so arranged that the relief-valve must be opened when the oil-valve is closed, and vice versa.

5. In a motor-vehicle provided with a hydrocarbon-motor, the combination of the cylinder relief-valve, the cylinder-lubricating valve, and the multiple valve controlling the outlet of oil-passages, of connections between said valves, and a hand-lever conveniently arranged and connected to operate all of said levers simultaneously.

700,769. DIVING VESSEL. THOMAS E. HAMAN, VANCOUVER, CANADA. Filed Dec. 29, 1901. Serial No. 57,692. (No model.)

Claim.—1. A diving vessel constructed in hollow oval form of a transparent material in two main parts which form a continuance of the general shape; a metallic joint-ring suitably connected to each part and having a curved connection pin within the other; a clamping eye attached to the center of the upper end; means for conveying air to within the vessel and for allowing the same to escape; a floor on the interior of the lower end; a propeller-shaft rotatable in a suitable gland-packed bearing in the wall of the vessel, each shaft having exterior to the vessel a propeller secured to it, and within, a means for rotating the shaft; a shield to protect the lower end; and a ballast-weight whereby the vessel may be submerged while suspended from above water.

2. In a diving vessel in hollow oval form, made of transparent material in two main parts, said parts uniting to form a cylindrical shape, the plane of division being horizontal and at right angles to the length of the device; a metallic joint-ring suitably connected to each part and adapted to screw one into the other; said device being susceptible of being submerged while suspended from above the surface of the water; and having means for a limited stability below water; a rubber pivotally movable in bearings in a bracket attached to the shell of the vessel; a shaft to actuate each rubber from the interior of the vessel; bevel-wheels rotatably connecting each shaft with the pivot or pin of the rubber; and means within the vessel of actuating each shaft and turning the rubber as desired.

3. In a diving vessel of hollow oval form constructed of suitable transparent material in two main parts having a curved junction toward the upper end; the lower part being constructed of metallic segments of the transparent material secured together by joint frames; the interposition of an elastic non-conducting material wherever the transparent material of the shell is joined to the metal of the frames or attachments; an exterior shield to the lower end; means whereby the vessel may be suspended during submersion; and means whereby it may be moved about and directed within a limited area.

4. A diving vessel, comprising a hollow body of transparent material, formed of two sections detachably joined, a propelling and steering mechanism therefor, and means for operating said mechanism, located within the hollow body, substantially as above and for the purposes described.

5. A diving vessel, comprising a body having a hollow oval form, adapted, when in its normal position, to hang with its axis in a vertical position, said body including a detachably-held upper end, having means for connecting with the suspending cord or cable, and an air supply and

exhaust pipe members attached to the said detachably-held upper end, for the purposes specified.

6. A diving vessel, comprising a hollow body, consisting of a bottom part having a floor or stand, an upper part detachably joined to the bottom part, by means of a suitable joint-ring suitably attached to each part and having threaded portions adapted to be revolved one into the other; a hand-shield for the lower end of said body; air supply and exhausting devices connected with the upper part; a driving and steering means at one side operable from within the body, and a grapple-engaging means at the other side including devices located within the body for cutting said grapple-engaging means to connect with or be disconnected from the grapple, as set forth.

7. A diving vessel, constructed in hollow oval form of transparent material, adapted to be suspended from a support above the water, with its axis normally in a vertical position, said body being formed in two parts, an upper and a lower, the lower being the larger, and the line of separation taking place on a plane at right angles to the axis; a propeller and rubber mechanism, centrally located at one side of said body, one above the other; and grapple means centrally located at the opposite side, and means for manually operating said device, as set forth.

700,770. BUB-BLE-LESS BOTTLE. FREDERICK J. HERRING, WILMINGTON, DE. Filed Nov. 22, 1902. Serial No. 57,721. (No model.)

Claim.—A bottle having a contracted neck 2 merging into a spherical portion which has an annular groove centrally about its circumference; a ball-stopper within said spherical portion and seated over the contracted portion of the neck, the circumference of said stopper having a circumferential groove, and a filling intermediate the lower wall of the spherical portion of the neck and said stopper, as set forth.

700,771. LACE-PAPER DOLLY. JOHN KINN, NEWARK, N.J. Filed Feb. 12, 1903. Serial No. 58,000. (No model.)

Claim.—1. A lace-patterned lace-paper dolly having situated within its border a substantially square design each of whose corners will lie equidistant from the two corners of the outer border of the dolly nearest to them, the edges of the lace substantially square design being formed in lace fabric than the portions of the dolly immediately outside of them.

2. A lace-paper dolly having situated within its outer border a substantially square design whose corners touch or approach near to the outer border of the dolly, the edges of the lace substantially square design being formed in lace fabric than the portions of the dolly immediately outside of them.

3. A four-sided leaf-paper dolly having situated within its outer border a substantially square design whose corners bisect the sides of the dolly and whose edges are formed so that they are less pliable than the portions of the dolly immediately outside of them.

4. A four-sided dolly of leaf-paper of such a design that a substantially square design is formed therein whose corners bisect the sides of the dolly and whose sides are formed enough stiffer than the portions of the dolly immediately outside of them to form bending edges.

5. A four-sided dolly of leaf-paper of such a design that a substantially square design is formed therein so that each corner of the inner design will be equidistant from the two corners of the outer border of the dolly nearest to them, the edges of the inner substantially square design being formed less flexible than the portions of the dolly immediately outside of them.

700,772. MOTOR-VEHICLE. BENJ. C. HUNT, Chicago, Ill. Filed Dec. 28, 1891. Serial No. 57,345. (No model.)

Claim.—1. In a vehicle of the class described, the combination of a main-frame portion, a bell-crank axle rockingly mounted in the rear and thereof, a central driving-wheel on each axle, and two rear supporting-wheels, rotatably mounted upon the bell-cranks of each axle, substantially as described.

2. In a vehicle of the class described, the combination of a main-frame portion, an axle rockingly mounted in the rear part thereof, a central driving-wheel loosely mounted upon each axle, two rear supporting-wheels rotatably mounted upon the bell-cranks of each axle, and means for pivotally connecting the bell-cranks with the main frame, substantially as described.

3. In a vehicle of the class described, the combination of a main-frame portion provided with front steering and guiding wheels, a bell-crank axle rockingly mounted in the frame at the rear part thereof and provided with two rotatable trailing wheels one on each of the bell-cranks, a central driving-wheel loosely mounted upon the center of each rear axle, and means pivotally connecting the bell-cranks with the main frame, substantially as described.

700,773. SPRING SHAFT-COUPLING. GUNTER C. HUNT, JR., Gunterville, Ind. Filed Mar. 10, 1891. Serial No. 57,345. (No model.)

Claim.—1. In a spring-coupling for shafts, the combination, substantially as set forth, of a driving and a driven flange, a stud projecting from the driving-flange toward the driven flange, a stud projecting from the driven flange toward the driving-flange, a normally flexed toggle having its extremities pivoted at said studs, and a spring connected with said toggle and serving to elastically resist the change of figure of the toggle under the influence of the driving strain.

2. In a spring-coupling for shafts, the combination, substantially as set forth, of a driving and a driven flange, a stud projecting from the driving-flange toward the driven flange, a stud projecting from the driven flange toward the driving-flange, a normally flexed toggle having its extremities pivoted at said studs, and a spring connected with said toggle and serving to elastically resist the change of figure of the toggle under the influence of the driving strain.

3. In a spring-coupling for shafts, the combination, substantially as set forth, of a driving and a driven flange, a stud projecting from the driving-flange toward the driven flange, a stud projecting from the driven flange toward the driving-flange, a normally flexed toggle having its extremities pivoted at said studs, and a helical spring having one of its ends attached to the intermediate pivot of the toggle and having its other end attached to one of said flanges, said spring serving to elastically resist the change of figure of the toggle under the influence of the driving strain.

4. In a spring-coupling for shafts, the combination, substantially as set forth, of a first flange, a second flange, a circular series of studs projecting from the first flange toward the second one, a circular series of studs, alternating with the first-mentioned studs and projecting from the second flange toward the first one, a series of inwardly-flexed toggles disposed between said flanges and having their forward extremities pivoted to studs of the first flange and their rearward extremities pivoted to studs of the second flange, a third circular series of studs carried by one of the flanges in a circle within the series of toggles, and helical springs having their inner ends attached to said third series of studs and having their outer ends connected to the intermediate pivots of the toggles.

5. In a spring-coupling for shafts, the combination, substantially as set forth, of a first flange, a second flange, studs projecting from the first flange toward the second flange, brackets carried by the first flange and engaging the outer projections of said studs, studs carried by the second flange and projecting toward the first flange, inwardly-flexed toggles with one of their extremities pivoted to said last-mentioned studs and their other extremities pivoted to the first-mentioned studs between the first flange and the brackets, inner additional studs carried by one of said flanges, and helical springs having their inner ends connected with said inner studs and having their outer ends connected with the intermediate pivots of said toggles.

6. In a spring-coupling for shafts, the combination, substantially as set forth, of a first flange, a second flange, studs projecting from the first flange toward the second flange, studs projecting from the second flange toward the first flange, inwardly-flexed toggles having members of unequal length and having one of their extremities attached to the first-mentioned studs and their other extremities attached to the last-mentioned studs, inner studs carried by one of said flanges, and helical springs having their inner ends attached to said inner studs and having their outer ends attached to intermediate pivots of said toggles.

700,774. FOLDING CRATE. WILLIAM C. HOLMES, Pittsburgh, Pa. assignor of one-half to Daniel Olmsted, Pittsburgh, Pa. Filed Dec. 24, 1890. Serial No. 46,914. (No model.)

Claim.—1. In a folding crate comprising the top, bottom, sides, and ends, the ends being composed of sections hinged together, the corner-

plates attached to the top and bottom and to which the end sections are pivotally connected, said corner-plates extending above the bottom and below the top, the sides of the crate being hinged to the top of the crate and adapted to swing downwardly and outwardly, the corner-plates limiting such outward movement of the sides, substantially as described.

2. A folding crate having a top, bottom, ends and sides, said sides being hinged to the under face of the top and adapted to open downwardly and outwardly, and a trough carried upon the outer face of the side adjacent to its lower end.

3. A folding crate comprising the top, bottom, ends and sides, the corner-plates, the straps attached to the ends, pivoted to the plate and to each other, each end being formed of hinged sections, and means for securing the crate in an open or folded position.

700,775. COMBINED RUBBER AND BUTTER-WORKER. THOMAS A. BOWEN, Orono, Minn. Filed Nov. 1, 1891. Serial No. 59,725. (No model.)

Claim.—1. The combination, with a revoluble drum, of rollers arranged therein and substantially parallel to each other, the axis of one roll being substantially coincident with the axis of the drum at one end of the drum, and the axis of the other roll being substantially coincident with the axis of the drum at the other end of the drum, means for operating said rolls, and means for operating said rolls.

2. The combination, with a revoluble drum, of a pair of rolls arranged in said drum, the axis of one roll being substantially coincident with the axis of the drum at one end of the drum, and the axis of the other roll being substantially coincident with the axis of the drum at the other end of the drum, means for revolving said drum, and means for revolving said rolls, substantially as described.

3. The combination, with a revoluble drum, of cross-heads arranged in said drum and each provided with a rotatable hub extending through a central opening in the head of the drum, a pair of rolls mounted in said cross-head, one of said rolls having a journal extending through the cross-head hub at one end of the drum, and the other roll having a journal extending through the cross-head hub at the other end of the drum, and means connected with said journals for driving said rolls.

4. The combination, with a revoluble drum, of cross-heads arranged in said drum, each of said cross-heads provided with a hub, projecting centrally through the head of the drum, means for locking said hub and cross-heads to the heads of the drum or to the frame of the machine, substantially as described.

5. The combination, with a revoluble drum, of cross-heads arranged therein, hubs or said cross-heads projecting centrally through the heads of the drum, a pair of rolls mounted in said cross-heads, the journal of one roll projecting through one of the cross-heads and its hub and a journal of the other roll projecting through the other cross-head and its hub, means for locking said cross-heads and hubs to the drum or to the frame of the machine, substantially as described.

frame of the machine, means for revolving said drum, and means for revolving said rolls, substantially as described.

6. The combination, with a revoluble drum, of cross-heads arranged within said drum, means extending centrally through the heads of the drum for supporting said cross-heads, a pair of rolls mounted in said cross-heads, each of said rolls having one of its journals extending through one head of the drum, means for revolving said drum, and means connected with said roll-journals for revolving said rolls.

7. The combination, with a revoluble drum, of cross-heads arranged in said drum and each having a hub projecting centrally through one head of the drum, a pair of rolls mounted in said cross-heads, one of said rolls having a journal extending through one of said hubs and the other roll having a journal extending through the other hub, means for revolving said drum, and means for connecting said journals with said drum, whereby said rolls may be simultaneously rotated from said drum, substantially as described.

8. The combination, with the revoluble drum, of the cross-heads mounted therein and each provided with a hub extending through a central opening in the head of the drum, a clutch arranged upon each of said hubs and adapted to lock the cross-head and hub to the drum or to the frame of the machine, means for revolving said drum and means for revolving said rolls while said cross-heads are held stationary, substantially as described.

9. The combination, with a revoluble drum, of cross-heads arranged in said drum and each having a hub projecting centrally through one head of the drum, a pair of rolls mounted in said cross-heads, one of said rolls having a journal extending through one of said hubs and the other roll having a journal extending through the other hub, beveled gears connected to said journals and means for operating said gears, substantially as described.

10. The combination, with the revoluble drum of the cross-heads provided with central hubs extending through the heads of the drum, a sliding clutch arranged to lock said cross-head to the drum or to the machinery-frame and rotatable rolls arranged to said drum and mounted in said cross-heads, substantially as described.

700,776. DRYING CAN OR CYLINDER. ALFRED A. HUTTON, St. Louis, Mo. Filed Aug. 5, 1891. Serial No. 70,914. (No model.)

Claim.—1. The combination with a drying can or cylinder provided with a hollow transverse, of a reservoir communicating with said transverse, a spirally-arranged open gutter or conductor on the lower side of the can or cylinder communicating with said reservoir, and means within said hollow transverse for conducting the discharge of water of condensation, substantially as described.

2. The combination with a drying can or cylinder provided with a hollow transverse, of a curved reservoir communicating with said transverse, a spirally-arranged open gutter or conductor on the lower side of the can or cylinder communicating with said reservoir and a spirally-arranged web or rib within said hollow transverse, substantially as described.

3. The combination with a drying can or cylinder provided with a hollow transverse, of a reservoir communicating with said transverse, a spirally-arranged open gutter or conductor on the lower side of the can or cylinder communicating with said reservoir, and a spirally-arranged web or rib within said hollow transverse, substantially as described.

arranged open gutter or condenser on the lower side of the can or cylinder communicating with said reservoir, and a web or rib within the hollow transverse and extended across the outlet-mouth of said reservoir, substantially as described.

4. The combination with a drying can or cylinder provided with a hollow transverse and with means for conveying water of condensation within the can to said hollow transverse, of means for conducting the discharge of the water of condensation through said hollow transverse, substantially as described.

700,777. CARBURETOR. EDWARD R. BROWN, Tipton, Ind. Filed Aug. 12, 1905. Renewed Oct. 2, 1905. Serial No. 77,816. (No model.)

Claim.—1. In a carburetor for gas-engines, an open, substantially conical chamber with downwardly-converging walls, air-pass leading to and from said conical chamber, a receiving and distributing trough located at or near the top of the converging walls of said conical chamber, means of introducing oil to and withdrawing same from said conical chamber, an exhaust-chamber of larger diameter than, and receiving said conical chamber, an annular escape-part at the top of said exhaust-chamber, an annular channel formed about the top of said exhaust-chamber, into which said escape-part leads, a port in the outer wall of said channel, means of admitting the condensed, exhaust products of a gas-engine to said exhaust-chamber, means of generating preliminary heat in the exhaust-chamber, about the walls of the generating-chamber; all constructed, combined and operating substantially as shown and described.

2. In a carburetor for gas-engines, a carbureting-chamber with downwardly-converging walls, an oil receiving and distributing trough located at the top of said carbureting-chamber, a cover superimposed above said carbureting-chamber, parts in said cover, adapted for the passage of air therethrough, an exhaust-chamber adapted to receive and envelop said carbureting-chamber, a port leading to said exhaust-chamber, a passage leading from said exhaust-chamber of greater circumference than said of the same area as said inlet-port, all constructed and combined substantially as shown and described.

3. In a carburetor for gas-engines, the combination of an exhaust-chamber, an inlet-part leading to said chamber, an escape-part leading from said chamber, an annular channel formed about said exhaust-chamber with which said escape-part communicates, a port communicating from said annular channel to the atmosphere; all so combined, located and proportioned as to draw or suck the steam of the exhaust of the gas-engine to which said carburetor is attached, substantially as shown and described.

700,778. CARBURETOR. EDWIN E. JAMES, Westend, Germany, assignor to Dr. Paul Mayer & Co., Berlin, Germany. Filed Aug. 12, 1905. Serial No. 77,807. (No model.)

Claim.—1. In a carburetor of the like and in combination, a plurality of pusher-bars having hammer-shaped heads, lay-levers to which said bars are pivoted, an adding mechanism, a special reversible stir for each set of lay-levers having a bar and adapted to drive the adding mechanism, a coupler for all the lay-levers, and a swinging frame for each set of lay-levers, the pusher-bars during the rotation of the stir touching always with one side surface the corresponding stir and with the other side the bar of the stir, substantially as described.

2. In a carburetor of the like and in combination, a plurality of pusher-bars having hammer-shaped heads, lay-levers to which said bars are pivoted, an adding mechanism, a special reversible stir for each set of lay-levers adapted to drive the adding mechanism, a coupler for all the lay-levers, and a swinging frame for each set of lay-levers, the pusher-bars during the rotation of the stir touching always with one side surface the corresponding stir and with the other side the bar of the stir, substantially as described.

3. In a carburetor of the like and in combination, a plurality of pusher-bars having hammer-shaped heads, lay-levers to which said bars are pivoted, an adding mechanism, a special reversible stir for each set of lay-levers adapted to drive the adding mechanism, a coupler for all the lay-levers, and a swinging frame for each set of lay-levers, the pusher-bars during the rotation of the stir touching always with one side surface the corresponding stir and with the other side the bar of the stir, substantially as described.

4. In a carburetor of the like and in combination, a plurality of pusher-bars having hammer-shaped heads, lay-levers to which said bars are pivoted, an adding mechanism, a special reversible stir for each set of lay-levers adapted to drive the adding mechanism, a coupler for all the lay-levers, and a swinging frame for each set of lay-levers, the pusher-bars during the rotation of the stir touching always with one side surface the corresponding stir and with the other side the bar of the stir, substantially as described.

700,779. STEERING APPARATUS FOR VEHICLES. ALBERT W. KENT, Boston, Mass. Filed Dec. 17, 1905. Serial No. 46,000. (No model.)

Claim.—1. In a wheeled vehicle, an upright shaft connected to the running-gear and a vertical shaft or extension of such shaft connected to the vehicle-body and telescoping with said upright shaft, for relative longitudinal without independent rotary movement, in combination with a steering-bar horizontally pivoted on such vertical extension, and with an adjustable locking device therefor, said extension having no vertical movement independent of the vehicle-body, substantially as set forth.

2. In a wheeled vehicle, a vertical shaft connected to the running-gear, a tubular vertical extension telescoping therewith, and a hollow column or guard surrounding such extension, and fixed to the vehicle-body, in combination with a steering-bar pivoted to said shaft, an adjustable locking-piece carried on said bar, and a lateral arm extending from said column or guard and notched marginally to engage such locking-piece when desired, substantially as set forth.

3. In a wheeled vehicle, a vertical shaft pivotedly connected to the running-gear, a metallic guard surrounding such shaft and a lateral arm notched marginally and supported by said column or guard, in combination with a tubular steering-bar connected to said shaft, a locking-piece mounted in a recess in said tubular bar and a movable rod or tube within such bar serving to operate said locking-piece, substantially as set forth.

4. In a wheeled vehicle, a vertical shaft connected to the running-gear, a hollow column or guard surrounding such shaft and a lateral arm or flange, notched marginally, adjacent to said guard, in combination with a steering-bar connected to said shaft by a horizontal pivot so as to oscillate such shaft by a lateral movement and to swing vertically without moving it, and with a suitable spring permitting horizontal movement of the steering-bar but controlling its vertical movement, substantially as set forth.

700,780. AX-HEAD. CALVIN EMM. WATSON, Pa. Filed Oct. 2, 1905. Serial No. 77,878. (No model.)

Claim.—As an improved article of manufacture an ax-head having a series of parallel grooves produced in its opposing faces adjacent to the cutting edge, said opposing faces being ground away above the series of grooves, and the intervening ridge portion extending across the upper ends of the grooves, substantially as set forth.

700,781. AUTOMATIC JOURNAL INSTRUMENT. EDWARD E. KLEIN, North Tonawanda, N. Y. Filed July 3, 1905. Serial No. 67,600. (No model.)

Claim.—1. The combination with a wind-chest having an opening of a sound-controlling member, a pneumatic communicating with said wind-chest, a cylinder operated by said pneumatic and passing through the opening of the wind-chest, and a collapsible coil applied to said opening and consisting of a tube having transverse bellows folds, said tube being secured at one end to the wind-chest and provided at its other end with a closed head which is caused to said cylinder, substantially as set forth.

2. The combination with a wind-chest and a movable sound-controlling member, of a motor-pneumatic for said member arranged in the wind-chest, an air-channel arranged parallel with said pneumatic, communicating with the latter and opening at its lower end into the wind-chest and at its upper end into the atmosphere, oppositely-opening valves applied to the lower and upper ends of said channel, a valve-rod movable lengthwise in said channel and arranged to open said valves alternately, and an actuating device for said rod, substantially as set forth.

3. The combination with a wind-chest and a movable sound-controlling member, of a motor-pneumatic for said member arranged in the wind-chest, an air-channel arranged parallel with said pneumatic, communicating with the latter and opening at its lower end into the wind-chest and at its upper end into the atmosphere, a valve controlling the outer end of said channel, a valve-rod extending lengthwise through said channel and arranged to engage said valve for opening it, a second valve

controlling the inner end of said channel and carried by said rod, and an actuating device for said valve-rod, substantially as set forth.

4. The combination with a wind-chest and a movable sound-controlling member, of a motor-pneumatic for said member arranged in the wind-chest, an air-channel arranged parallel with said pneumatic, communicating with the latter and opening at its lower end into the wind-chest and at its upper end into the atmosphere, a valve controlling the outer end of said channel, a valve-rod extending lengthwise through said channel and arranged to engage said valve for opening it, a second valve controlling the inner end of said channel and carried by said rod, an air-chamber having a flexible diaphragm arranged to engage said valve-rod, and a truss having a dust leading to said air-chamber, substantially as set forth.

5. The combination with a wind-chest and a movable sound-controlling member, of a motor-pneumatic for said member arranged in the wind-chest, an air-channel arranged lengthwise on the outer side of said pneumatic and provided in its upper side with a dust leading into the pneumatic, the lower end of said channel opening into said wind-chest and its outer end opening into the atmosphere, oppositely-opening valves applied to the ends of said channel, a sliding valve-rod arranged lengthwise in said channel, carrying the inner valve of the channel and arranged to open the outer valve thereof when the inner valve is closed, an air-chamber having a flexible diaphragm arranged to engage said valve-rod, and a truss having a dust leading to said air-chamber, substantially as set forth.

6. The combination with a wind-chest and a movable sound-controlling member, of a motor-pneumatic for said member arranged in the wind-chest, an air-channel communicating with said pneumatic and opening at its lower end into said chest and at its upper end into the atmosphere, oppositely-opening valves applied to the ends of said channel, a valve-rod movable lengthwise in said channel, carrying the inner valve of the channel and provided at its outer end with an adjustable stem arranged to bear against the outer valve of said channel, and an actuating device for said valve-rod, substantially as set forth.

7. The combination with a wind-chest having a removable front plate, of a board or support arranged horizontally in the wind-chest and provided with a series of horizontal air-channels which open at their front ends into the wind-chest and at their rear ends into the atmosphere, a series of motor-pneumatics arranged upon said channelled board and communicating with the channels thereof, valves applied to the front and rear ends of each of said channels, a valve-rod for operating said valves arranged in each channel and extending beyond the front and thereof, and air-chambers carried by the removable front plate of the wind-chest and provided with flexible diaphragms which are arranged to operate said valve-rod, substantially as set forth.

700,782. SIDE COUPLING FOR RAILROAD-CARS. FLEISS KERN, Elm, Germany. Filed Feb. 2, 1905. Serial No. 68,900. (No model.)

Claim.—In a side coupling for railroad-cars, the combination of a square bar d, arranged underneath the car, sliding pieces c, adapted to be longitudinally displaced by lever mechanism (outside of the car, horizontal coupling-hooks b, pivoted in a slot of the bar, the said hooks having clamping impact-surfaces and being provided with lateral elevations or shoulders / against which the springs e, arranged upon the said sliding pieces, are adapted to bear, upon the forward movement of the sliding pieces c, whereby the coupling-hooks are laterally displaced, and of counter-springs e adapted to bring back and retain the hooks in a parallel position with the bar d, all essentially as and for the purpose set forth.

700,788. GALVANO-ELECTRO-THERAPEUTIC CHAIR. ADOLF KLEIN, Berlin, Germany, assignor to The Firm of Handelsgeellschaft Adolf Winter, Berlin, Germany. Filed Mar. 19, 1905. Serial No. 68,970. (No model.)

Claim.—In a galvanic-electric therapeutic chain, the combination of a plurality of chain-links, each consisting of a copper and a zinc cup separated by a moisture-absorbing material, the like poles of the galvanic elements, formed by the links, being connected to each other, with a galvanic dry battery inserted between two adjacent links of the chain, the poles of which battery are connected to the like poles of the chain, substantially as described and for the purpose set forth.

700,784. AUTOMOBILE. ALBERT L. KELL, Camden, N. J. Filed Mar. 22, 1901. Renewed Dec. 9, 1901. Serial No. 55,269. (No model.)

Claim.—1. In an automobile or similar motor-vehicle, a frame, consisting of longitudinally-arranged transverse members, each brace, consisting of an upper horizontal member, bowed or belled downward to receive the bearings of an explosive-engine, and a lower arch-like member opening the ends of the upper horizontal member and supporting the bowed portion thereof, a front and rear axle connected by said frame, a body supported directly upon the axles, an oil tank or receptacle supported on said body, an engine supported directly by the frame, and a flexible connection between the tank and the engine, substantially as and for the purpose described.

2. In an automobile or similar motor-vehicle, a frame, consisting of transverse-like braces arranged to connect the axles of the vehicle, each brace being downwardly bowed, an engine having its bearings supported by the bowed portion of the braces, a body supported directly upon the axles and disconnected from the frame, a tank or receptacle carried by the body, mixing and explosion chambers for the engine, projecting upward from the engine into the body of the vehicle and a flexible connection extending from the mixing and explosion chambers to the tank or receptacle, substantially as and for the purpose described.

3. In an automobile or similar motor-vehicle, a frame provided with braces arranged to connect the axles of the vehicle, an engine supported by said braces, a body carrying a tank or receptacle, mixing and explosion chambers for the engine extending therefrom into the body of the vehicle, and a flexible connection from the mixing or explosion chambers to said tank or receptacle, substantially as and for the purpose described.

700,785. MUFFLER FOR ENGINES OR OTHER MACHINES. ALBERT L. KELL, Camden, N. J. Filed Mar. 22, 1901. Renewed Dec. 9, 1901. Serial No. 55,261. (No model.)

Claim.—1. A muffler, comprising a tube constituting the main body of the muffler, a frusto-conical tube extending one end of said tube with the exhaust-pipe and constituting an expanding-chamber for the exhaust-gases, a partition located at the inlet end of the expanding-chamber and within the body of the muffler, said partition having a series of openings, each of which is substantially equal in cross-sectional area to the area of the exhaust-pipe, and a series of tapered tube-like fingers extending within the body of the muffler from the openings in said partition, the area of the conical outlet of the fingers being substantially equal to the area of the inlet of one of said fingers, and the inlet of one of said fingers being arranged in alignment with the exhaust-pipe, substantially as and for the purpose described.

2. A muffler, comprising a tube constituting the main body of the muffler, a partitioned partition closing the outlet end of said body, a frusto-conical tube connecting the entrance end of said body with the exhaust-pipe, a partition arranged at or near the entrance end of said body and provided with a series of openings corresponding to the opening in the exhaust-pipe, one of said openings being in alignment with the exhaust-pipe and a series of tapered tubes projecting from the openings in the partition into the body of the muffler, the area of the conical outlet of said fingers being approximately equal to the area of the exhaust-pipe opening, substantially as and for the purpose described.

3. A muffler, comprising a tube constituting the main body of the muffler, a frusto-conical tube connecting one end of said body to the exhaust-pipe, a partition located between the frusto-conical tube and the body of the muffler, said partition having a series of openings each corresponding in area to the area of the exhaust-pipe outlet, and a series of tapered open-ended tubes extending from said openings into the body of the muffler, the walls of each tapered tube being perforated, substantially as and for the purpose described.

4. A muffler, comprising a tube constituting the main body of the muffler, a frusto-conical tube connecting one end of said body with the exhaust-pipe, a partition arranged within the main body adjacent to the frusto-conical tube, said partition having openings each corresponding in area to the area of the exhaust-outlet, a series of tapered tubes projecting from the openings into the main body of the muffler, a second partitioned partition and a second series of tapered tubes projecting therefrom and corresponding in the first partition and first series of tapered tubes, said second partition and tapered tubes being arranged within the main body of the muffler and intermediate of the first, substantially as and for the purpose described.

700,786. DRIVEN MECHANISM FOR AUTOMOBILES. ALBERT L. KELL, Camden, N. J. Filed Apr. 2, 1901. Renewed Dec. 9, 1901. Serial No. 55,262. (No model.)

Claim.—In an automobile, a shaft driven directly by the main driving-shaft, a cleave surrounding the driven shaft, a sprocket-wheel carried

to said cleave, a housing carried by said cleave, a disk carried by the driven shaft, a split ring secured to said disk, and extending within the housing, a toggle connection between the free ends of said ring and means for expanding said toggled connection to clamp the band and disk to the housing, substantially as and for the purpose described.

700,787. LIQUID-SOAP CONTAINER. LEWIS G. LAMMART, Brooklyn, N. Y. Filed Apr. 25, 1901. Serial No. 57,450. (No model.)

Claim.—1. A liquid-soap container, the same consisting of a receptacle for the soap, pivoted to permit its opening upward, a closure for said opening fixed in each position as normally to close the same, and a device carried upon said receptacle for tilting the same, substantially as and for the purpose described.

2. In a liquid-soap container, the combination of a bracket, a collar carried thereby on a substantially horizontal pivot, a tilting device upon said collar, a receptacle held by said collar, and a closure carried by the prolongation of said bracket, against which the weight of the receptacle causes the latter to be normally closed, substantially as described.

3. In a liquid-soap container, the combination of a bracket, a collar carried thereby on a substantially horizontal pivot, a receptacle held by said collar, and a closure fixed in each position that the weight of said receptacle normally forces the opening of the latter against said closure, substantially as described.

700,788. KEY-LOCK FOR DOOR. HOWARD R. LEVITT, Montclair, N. J., and JOHN W. FULTON, Apple River, Ill. Filed Jan. 24, 1902. Serial No. 57,282. (No model.)

Claim.—1. The combination with the connection members A and B, having sliding bolt-openings; of the bolt U having a bifurcated outer end, the latch D having a shaft pivotedly hung on the said outer end, and a weighted extension, and the washer E having a bolt-opening, a prong member provided with a disk engaging with the bolt-opening, the inner side of said washer having means projecting over and engaging the

member A to prevent it from swinging on or with the bolt, as shown and described.

2. The combination with the parts A and B, and the bolt U, said bolt having a bifurcated extension; of the latch D, pivotedly hung on said bifurcated bolt end and having a weighted outer end, adapted to be swung into longitudinal alignment with the bolt, and the washer E apertured to loosely hang on the bolt, said washer having a slotted opening with its bolt-opening, and having on its inner face projections to engage the opposite edges of the member A, all being arranged substantially as shown and for the purpose described.

700,789. ORG-CHUTE AND TRAP-DOOR. JOHN A. LEBALL and HENRY MATTHEW, Two Harbors, Minn. Filed Dec. 27, 1901. Serial No. 57,598. (No model.)

Claim.—1. In a mechanism for regulating the flow of ore or material in transporting same from one receptacle to another, the combination of two rods extending from the top of a pocket down to the lower end of the same and there secured, suitable trap-doors being secured on said rods, said doors being provided with suitable pins or projections, suitable cog-wheels being secured on the upper end of said rods, said cog-wheels intermeshing with each other, a suitable lever being secured on one of said rods, a suitable stopper to engage said lever, a smaller cog-wheel intermeshing with one of the main cog-wheels secured on the rods, said smaller cog-wheel being actuated by a lever, substantially as described and shown.

2. In a mechanism for regulating the flow of ore or material from a pocket or other receptacle, the combination of rods provided in or about the sides of a pocket, extending from the top to the bottom of same, doors being secured on the lower end of said rods and suitable cog-wheels being provided at the upper end of said rods, said cog-wheels intermeshing each other, a smaller cog-wheel intermeshing one of said large cog-wheels, both of said cog-wheels being operated by a lever, which lever engaging a suitable stopper, a suitable sliding-bar provided with a series of projecting pins preferably placed at right angles, substantially as described and shown.

700,790. MECHANISM FOR OPERATING MACHINES FOR ATTACHING BUTTORS. DR. THOMAS LOWN, Boston, Mass., assignor to the Consolidated Fastener Company, Portland, Me. Filed May 24, 1902. Serial No. 17,795. (No model.)

Claim.—1. In mechanism for operating machines for attaching buttors, or for other purposes, the combination of a constantly-driven mechanism; a toggle-joint lever; means for operating said lever, said means being normally out of operative connection with the driven mechanism; and a suitable-actuated power snap-mechanism for positively moving said means into operative connection with the driven mechanism, said mechanism automatically preventing a movement in excess of a single revolution of the driven mechanism, regardless of the position of the toggle.

2. In mechanism for operating machines for attaching buttons, or for other purposes, the combination of a constantly-driven mechanism; a toggle-joint lever; means for operating said lever, said means being normally out of operative connection with the driven mechanism; and a treadle-actuated power stop mechanism for positively moving said means into operative connection with the driven mechanism, said connection being held substantially non-yielding during the major portion of the revolution of the driven mechanism, said mechanism substantially preventing a movement in excess of a single revolution of the driven mechanism, regardless of the position of the treadle.

3. In mechanism for operating machines for attaching buttons, or for other purposes, the combination of a constantly-driven mechanism; a toggle-joint lever; means for operating said lever, said means being normally out of operative connection with the driven mechanism; a treadle-actuated power stop mechanism for positively moving said means into operative connection with the driven mechanism; and means for automatically disengaging said connection at a predetermined point in the revolution of the driven mechanism irrespective of the position of the treadle.

4. In mechanism for operating machines for attaching buttons, or for other purposes, the combination of a constantly-driven mechanism; a toggle-joint lever; means for operating said lever, said means being normally out of operative connection with the driven mechanism; a treadle-actuated power stop mechanism for positively moving said means into operative connection with the driven mechanism; and means for automatically disengaging said connection at a predetermined point in the revolution of the driven mechanism irrespective of the position of the treadle, said means being operated at a plurality of points.

5. In a mechanism for operating machines for attaching buttons, or for other purposes, a toggle-joint lever having a treadle pocket or notch, a treadle in said pocket and power-driven mechanism mounted to intermittently impart a movement to said lever, said mechanism being independent of and having no positive connection with said toggle, whereby the lever may be moved independently by treadle or power-driven mechanism.

6. In a mechanism for operating machines for attaching buttons, or for other purposes, a treadle-actuated stop mechanism comprising a splined driving-shaft and a loose hub-toothed pulley on said shaft, in combination with an ejector and treadle-actuated sliding latched dog automatically held in operative position during the greater portion of the rotation of the shaft, and tooth-disengaging mechanism operating automatically regardless of the position of the treadle; substantially as shown and described.

7. In a mechanism for operating machines for attaching buttons, or for other purposes, a treadle-actuated stop mechanism comprising a splined driving-shaft, and a loose hub-toothed pulley on said shaft, in combination with a sliding dog latched to said shaft, springs for normally holding said dog out of engagement with said pulley, a plate having a dog-receiving depression, a treadle-actuated ejector-rod U, and means for automatically disengaging said dog and pulley regardless of the position of the treadle, substantially as shown and described.

8. In a mechanism for operating machines for attaching buttons, or for other purposes, a stop mechanism comprising a splined driving-shaft, a loose hub-toothed pulley on said shaft, in combination with a sliding dog latched to said shaft and having a cam-lug A, a cam-plate having a dog-receiving depression and a lug-engaging cam, and an ejector whereby said shaft makes one and but one revolution at each stroke of the ejector, substantially as shown and described.

9. In a mechanism for operating machines for attaching buttons, or for other purposes, a stop mechanism comprising a splined driving-shaft, a spring-actuated cam-pin A, and a loose hub-toothed pulley mounted on said shaft, in combination with a sliding dog latched to said shaft and normally held in inoperative position, a cam-plate having a dog-receiving depression, and a treadle-actuated ejector-rod U, substantially as shown and described.

10. In a mechanism for operating machines for attaching buttons, or for other purposes, a toggle-joint lever and a roller C, thereon, in combination with a driven shaft, a cam fixed on said shaft, a spring-pin B slidable thereon, a power stop mechanism for driving the shaft, comprising a loose hub-toothed pulley, a sliding latched dog normally held in inoperative position, a cam-plate having a dog-receiving depression, and a treadle-actuated ejector-rod, all substantially as shown and described.

11. In a mechanism for operating machines for attaching buttons, or for other purposes, a toggle-joint lever and a buffer C carried thereby, in combination with a power-driven cam, said buffer being adapted to operate on the active face of said cam, substantially as shown and described.

12. In a mechanism for operating machines for attaching buttons, or for other purposes, a treadle-actuated stop mechanism comprising a splined driving-shaft, a loose pulley having a spring-pressed tooth in its hub, in combination with an ejector and treadle-actuated sliding latched dog normally held out of engagement with said tooth and automatically held latched in operative position during the greater portion of the re-

vision of the shaft, and tooth-disengaging mechanism operating automatically regardless of the position of the treadle, substantially as shown and described.

700,791. HEATER. CLARENCE C. LEONARD, Halifax, Canada. Filed Oct. 24, 1901. Serial No. 73,572. (No model.)

Claim.—A water-heater comprising a fire-pot, a grate at the base of the fire-pot, provided with a large, central opening, the hollow, cone-shaped, combined water-chamber and fuel support and deflector arranged in the center of the fire-box with its reduced upper end and its lower end so arranged with respect to the central opening in the grate as to permit the escape of ashes and prevent the escape of fuel through said opening, a water-supply pipe connected to the wall of the heater and the combined water-chamber and fuel support and deflector, and a discharge-pipe also connected to said water-chamber and fuel support and deflector and the wall of the heater.

700,792. MAGAZINE-CAMERA. DAVID A. LOWTHIAN, London, England. Filed Oct. 31, 1901. Serial No. 59,627. (No model.)

Claim.—1. A means for loading and unloading photographic cameras with plates comprising a case adapted to contain the plates placed alternately together with their backing-sheets and having its front side formed from a flexible strip of non-elastic material so attached as to be easily torn away from the case in order to uncover the foremost plate therein, and a camera provided at its back end with a door for introducing and with a shelf for supporting the said case and further provided with a bar sliding light-tightly therein so placed as to admit of receiving the plates after their exposure, the said sliding bar being provided with a sliding lid, as set forth.

2. A photographic camera comprising a transversely-arranged shelf d forming a ledge for supporting the plates, a bar c—with movable lid c'—sliding light-tightly within the camera between the bottom thereof and the shelf d and adapted to contain the plates after exposure, a door e formed to allow access to the plate-holding compartment formed between the walls of the camera and the shelf d in combination with a case c adapted to be placed on the shelf d within the camera and to contain plates e placed alternately with their backing-sheets f and having a front side formed from a flexible strip g of non-elastic material attached to the case by covering-strips h of weaker material than the strip g, which strip g is doubled on itself in order that its free end may be passed over the shelf d to protrude from the camera and on being pulled uncover the first plate ready for exposure, as set forth.

700,793. PROCESS OF STIFFENING AND MAKING IMPERVIOUS TO WATER STARCH-FILLER AND IRONED LAUNDRY-FINISHED CLOTHING OF ROBIN OF COLLARS, CUFFS, &c. HENRY A. HALL, New York, N. Y., assignor to the American Company, Albany, N. Y., a Corporation of New York. Filed Apr. 22, 1902. Serial No. 56,062. (No specimens.)

Claim.—1. The process above described for increasing the stiffness of a starch-filled and laundry-finished collar, cuff, &c., by means of soluble cotton and so that said stiffness arising from the presence of said soluble cotton may readily be removed from the same by washing in heated alkaline water, the same consisting in forcing, under pressure of suitable revolving flexible rollers, into the substance of the body of said starch-filled and laundry-finished article a solution of soluble cotton and amylose, acetone, &c., in condition of consistency described and freeing the surface of said article from all appearance of said solution, substantially as herein described.

2. The process above described for increasing the stiffness of a starch-filled and laundry-finished collar, cuff, &c., and making the body of the same impervious to perspiration and to water, in natural condition, and so that the said stiffness and imperviousness, arising from the presence of said soluble cotton, may readily be removed from the body of the said article by heated alkaline-water washings, the same consisting in forcing, (under pressure of suitable revolving flexible rollers,) into the substance of the starch-filled and laundry-finished body, of the article, a solution of soluble cotton and amylose, acetone, &c., in condition of consistency described and freeing the surface of the article from all appearance of said solution, substantially as described.

3. The product of the herein-described process, the same consisting of a collar, cuff, &c., having a starched and ironed and laundry-finished body of fabric which is stiffened over normal laundry-produced stiffness and made impervious to perspiration and water, in natural condition, by means of soluble cotton contained in a suitable quantity in the combined substance of the body of said article, but wholly absent, in appearance from the surface of the same, and adapted to be wholly removed from said body by heated alkaline-water washings as practiced for washing soiled articles, substantially as described.

700,794. BUILDING. JOHN A. MARTIN-COOK, Arlington, N. Y., assignor of one-half to Thomas R. Inman, New York, N. Y. Filed Feb. 12, 1902. Serial No. 54,728. (No model.)

Claim.—A building composed of two rows of obliquely-set wings, opening each other, and forming intermediate halls, exterior walls connecting adjoining wings at their angles, a light-shaft within the center of each hall, a surrounding continuous landing, and a staircase within the light-shaft induced by the landing, substantially as specified.

700,795. LINE SPREADER AND GUIDE. THEODORE E. HATHAWAY, Milwaukee, Wis., assignor to Hiram L. Lewis & Adams and Samuel J. Hall, Waterbury, Conn., and David G. Webster, Oyster, N. J., a Partnership. Filed Sept. 23, 1901. Serial No. 71,002. (No model.)

Claim.—1. A spreader or guide for a line or strap, consisting of side bars or members, each provided at a corresponding end with an extension projecting laterally at an angle therefrom, the said extensions being pivoted together, and each extension being prolonged laterally beyond the pivotal point, said prolongations adapted to register and overlap each other, when the side bars or members are made to approach each other, a roller being located at the opposite ends of the side bars or members, said roller being rotatably engaged with the side bars or members, when said side bars or

members are made to approach each other, and said roller being disengaged from the side bars or members when the latter are turned on their pivot away from each other, and means constructed to releasably engage the extensions, when the side bars or members are turned in a direction to cause the extensions to approach each other, and the prolongations thereof to overlap.

2. A spreader or guide for a line or strap, consisting of side bars or members each provided at a corresponding end with a slotted extension projecting laterally at an angle therefrom, the said extensions being pivoted together, and the opposite end of each side bar or member provided with an inwardly-extending stud, a roller provided with an axial opening which the studs are adapted to engage, when the side bars or members are turned in a direction to bring the studs toward each other, and a strap, or other securing means, adapted to be passed through the slot of the extension, when the side bars or members are turned in a direction to cause the extensions to approach each other and the respective slots to register.

3. A spreader or guide for a line or strap, consisting of side bars or members each provided at a corresponding end with a slotted extension projecting laterally at an angle therefrom, the said extensions being pivoted together, a roller located at the opposite ends of the side bars or members, said roller being rotatably engaged with the side bars or members, when said side bars or members are made to approach each other, and said roller being disengaged from the side bars or members when the latter are turned on their pivot away from each other, and a strap, or other securing means, adapted to be passed through the slot of the extension, when the side bars or members are turned in a direction to cause the extensions to approach each other and the respective slots to register.

4. A spreader or guide for a line or strap, consisting of side bars or members each provided at a corresponding end with an extension projecting laterally at an angle therefrom, the said extensions being pivoted together, and each extension being prolonged laterally beyond the pivotal point, said prolongations adapted to register and overlap each other when the side bars or members are made to approach each other, and the opposite end of each side bar or member provided with an inwardly-extending stud, a roller provided with an axial opening which the studs are adapted to engage when the side bars or members are turned in a direction to bring the studs toward each other, and means constructed to releasably engage the extensions, when the side bars or members are turned in a direction to cause the extensions to approach each other and the prolongations thereof to overlap.

700,796. ONE-CONTROLLED TIME-INFLATOR. RAYMOND S. HOLTMAN, Buffalo, N. Y. Filed Dec. 24, 1900. Renewed Oct. 7, 1901. Serial No. 77,008. (No model.)

Claim.—1. The combination with a wheel-holding jaw or rack, of an air-supply conduit, an air-delivery nozzle which is movable toward and from said jaw or rack, means for guiding said nozzle, and a one-controlled mechanism whereby the supply of air to said nozzle is controlled, substantially as set forth.

2. The combination with a wheel-holding jaw or rack, of an air-supply conduit, an air-delivery nozzle which is movable toward and from said jaw or rack, means for guiding said nozzle, a valve arranged in the air-supply conduit, and a one-controlled mechanism whereby said valve is opened, substantially as set forth.

3. The combination with a wheel-holding jaw or rack, and a one-controlled valve which controls an air-supply conduit, of a movable air-delivery nozzle, which is connected with said conduit and which is movable toward and from the jaw to be inflated, and a spring whereby the nozzle is yieldingly held in its forward or backward position, substantially as set forth.

4. The combination with a wheel-holding jaw or rack, of an air-

supply conduit, an air-delivery nozzle having its discharge end movable toward and from the mouth of said jaw or rack for locking the wheel in the same, means for guiding the discharge end of said nozzle, a valve which controls the flow of the air to said nozzle, and a coin-controlled mechanism whereby said valve is opened, substantially as set forth.

5. The combination with a wheel-holding jaw or rack, of an air-supply conduit, a sliding air-delivery nozzle arranged on one side of said jaw or rack and having a bent discharge end which flows the mouth of said jaw or rack, means for guiding said nozzle, a valve which controls the flow of the air to said nozzle, and a coin-controlled mechanism whereby said valve is opened, substantially as set forth.

6. The combination with a wheel-holding jaw or rack and a fixed air-supply conduit connected therewith, of a sliding air-delivery nozzle arranged on one side of said jaw or rack and having a bent discharge end which flows the mouth of said jaw or rack, means for guiding said nozzle, a flexible pipe connecting said fixed conduit with said nozzle, a valve which controls the flow of the air to said nozzle, and a coin-controlled mechanism whereby said valve is opened, substantially as set forth.

7. The combination of a wheel-holding jaw or rack, an air-delivery nozzle movable toward and from said jaw or rack, air-supply means controlled by the movement of said air-delivery nozzle, and coin-controlled mechanism whereby the movement of said delivery-nozzle is controlled, substantially as set forth.

700,797. OIL-ATOMIZER. HARRY P. MOHR, Chicago, Ill., assignor of one-half to James G. Long, Chicago, Ill. Filed July 17, 1901. Serial No. 28,197. (No model.)

Claim.—1. A lubricating device for steam-engines and like machinery, comprising in combination a steam-pipe, an oil-atomizer comprising a feed-pipe, a conical member having the surface exposed to the direct action of the steam, and a receptacle in the upper part of said member into which the oil is adapted to be fed and from which it flows to the outer exposed surface of the conical part of the member, substantially as described.

2. The combination with a steam-pipe, of an oil-atomizer therein comprising a feed-pipe, and a conical member having an exposed surface and an upturned lower edge or rim to retard and evenly distribute the oil from said surface of the member, substantially as described.

3. The combination with a steam-pipe, of an oil-atomizer therein comprising a feed-pipe, and a conical member having a depression in its upper end into which the oil is fed and an upturned rim at its lower end, substantially as described.

4. The combination with a feed-pipe, of a bell-shaped member, a connecting-joint to secure the said member to the pipe, the member having a depression in its top over which the end of the feed-pipe terminates, and openings from the edge of said depression to the surface of the bell-shaped member, substantially as described.

5. The combination with a feed-pipe, of an angle-joint connected therewith, a conical member having a depression in its top, threaded into the lower end of said joint, registering grooves in the threaded portions of both parts, the said pipe terminating over said depression, whereby oil from the pipe first drops into the receptacle and then overflows and passes through the grooves to the outer surface of the cone, substantially as described.

6. The combination with a feed-pipe, of an angle-joint connection secured thereto, a conical part secured in the lower opening of said connection, said part having a depression or pan in its upper end and an upturned lower edge, and communicating passages from the edge of said depression or pan to the outer surface of said cone, substantially as described.

7. A steam-engine lubricator comprising in combination with a steam-pipe leading to the parts to be lubricated, of a spraying device located in said steam-pipe and having a spraying-surface exposed on all sides to the action of the passing steam and out of contact with the side walls of

the pipe, the lower edge of said surface being formed to prevent the collection of the unexpended oil in drops, a feed-pipe to conduct the lubricating-oil to said spraying device, and means also within the steam-pipe for detaining the oil before feeding it to the spraying-surface whereby the oil is heated, substantially as described.

8. In a steam-engine lubricator, the combination with a steam-pipe leading to the steam-cylinder, of an oil-atomizer located within the pipe comprising an inclined spraying-surface adapted to be wholly exposed to and heated by the passing steam to substantially the temperature of steam and upon which surface the oil is adapted to be fed in a film-like condition, and means for retarding the passage of the oil through the atomizer whereby it is heated to substantially the temperature of steam before reaching said spraying-surface, the lower edge of said surface being formed to prevent the gathering of the unexpended oil in drops, substantially as described.

9. A steam-engine lubricator, comprising in combination a steam-pipe leading to the cylinder of the engine, and an oil-atomizer within the pipe comprising a hollow conical member exposed on its inner and outer surfaces to the direct action of the steam, a feed-pipe to supply the oil to the atomizer, and means for detaining the oil for a short period before it reaches the exposed surface of said member, substantially as described.

10. In an oil-atomizer, the combination with a conical spraying member having an exposed outer surface, a cap for the reception of the oil before it reaches said surface, and a raised rim at the lower edge of said surface, substantially as described.

11. The combination with an oil-fed pipe, an angle-joint connection secured thereto, a hollow conical part secured in the lower opening of said connection, said part having a depression in its upper end, and communicating passages from said depression to the upper part of the outer surface of said cone, substantially as described.

12. The combination with a vertical portion of a steam-pipe in which the steam passes downwardly, of a feed-pipe extending at right angles into the steam-pipe, an elbow-joint fitted to the extended end of the feed-pipe and turned downward, the end of said feed-pipe being slanted so as to terminate substantially over the center of the downward opening of said elbow, a conical part secured into said lower end of the elbow and having a depression in its upper end into which the oil from the feed-pipe is adapted to fall, and passages leading from the depression to the surface of the cone, substantially as described.

700,798. COUPLING FOR HOSE-PIPES. J. J. MOHR, JR., Boston, England. Filed July 2, 1901. Serial No. 28,198. (No model.)

Claim.—1. A coupling for hose and pipes comprising in its construction a body, a number of legs projecting therefrom, a revolving collar placed behind the body, a number of latches operated by said collar to engage the opposite part of the coupling and springs to move said collar in one direction, substantially as described.

2. In a coupling for hose and pipes the combination with the body a and a number of legs projecting longitudinally therefrom provided with recesses as in their base, of a movable ring *f* to which the latches *g* are attached and springs *c* placed behind the latches *g* in the recesses *a* to operate them substantially as described.

700,799. APPARATUS FOR UNLOADING SHIP'S CARGOES. ARTHUR HILLMAN, San Francisco, Cal. Filed Nov. 21, 1901. Serial No. 28,199. (No model.)

Claim.—1. In an apparatus of the character described, the combination of a frame, means for supporting the lower end of the frame, guy-rope attached to the upper portion of the frame for maintaining said frame in an upright position, a chute, an operating-platform secured to the upper end of the chute, and means for supporting said chute from the upper end of the frame, substantially as described.

2. In an apparatus of the character described, the combination of a frame, means for supporting the lower end of the frame, guy-rope attached to the upper portion of the frame for maintaining said frame in an upright position, a chute, an operating-platform secured to the upper end

of the chute, means for supporting said chute from the upper end of the frame, and means for adjusting the elevation and inclination of said chute, substantially as described.

3. In an apparatus of the character described, the combination of a frame, means for supporting the lower end of the frame, guy-rope attached to the upper portion of the frame for maintaining said frame in an upright position, a chute, an operating-platform secured to the upper end of the chute, means for supporting said chute from the upper end of the frame, and wheels attached to said frame, substantially as described.

4. In an apparatus of the character described, the combination of a frame, means for removably supporting the frame in an upright position, a chute, means for supporting the chute from the upper end of the frame, and a platform secured beneath the upper end of the chute and projecting beyond the side of the chute to form a support for an operator, substantially as described.

5. In an apparatus of the character described, the combination of a frame comprising side pieces, a top piece, and a connection between the lower portions of said side pieces, a chute extending through the frame in the space between said top piece and connection, means for adjusting the position of said chute in said space, and a wheel-axle secured upon said frame at one end of said space, said axle having wheels freely rotatable on its ends, substantially as described.

700,800. MULTIPLEX-TELEGRAPH CIRCUIT. LAWRENCE A. McCAHNT, Brooklyn, N. Y. Filed Nov. 15, 1901. Serial No. 28,712. (No model.)

Claim.—1. In a multiplex-telegraph circuit, the combination of a circuiting instrument, consisting of electromagnets, an armature, common to said magnets, contact-arm, a contact-post, separating the latter, and the adjustable springs, co-operating with said contact-arm, with the controlling instrument and its local circuit, and means actuated by said local circuit, for varying the resistance of the artificial line, substantially as set forth.

2. In a multiplex-telegraph circuit, the combination of a circuiting instrument, consisting of electromagnets, an armature, common to said magnets, the contact-arm, a contact-post, separating the latter, and the adjustable springs, co-operating with said contact-arm, with the controlling instrument and its local circuit, and the main and artificial line, and means actuated by said controlling instrument, for varying the resistance of the artificial line, substantially as set forth.

3. In a multiplex-telegraph circuit, the combination of a circuiting instrument, consisting of electromagnets, an armature, common to said magnets, contact-arm, contact-post, and adjustable springs, with the controlling instrument, its local circuit, the local magnets, in said local circuit, and the automatic circuit, all substantially as and for the purpose set forth.

4. In a multiplex-telegraph circuit, the combination of a circuiting instrument, consisting of electromagnets, an armature, common to said magnets, the contact-arm, a post, separating the latter, and the adjustable

springs, co-operating with said contact-arm, with the controlling instrument and its local circuit, the main battery, the receiving instrument, the main and artificial line and condenser, and means in said artificial line, operated by said controlling instrument for varying the resistance of the artificial line, substantially as set forth.

5. In a multiplex-telegraph circuit, the combination of a controlling instrument, having coils of wire, a needle, common to said coils and provided to an electromagnet, local contact-stops, for said needle, and said magnet, connected in the artificial line, with the local circuit, the local magnets, in said circuit, the main battery, the main and artificial line, and means in said artificial line for adjusting the resistance of the latter, that the resistance of the main line and artificial line are always equal, all substantially as and for the purpose set forth.

700,801. UNDERGARMENT. EDWARD FRIEDMAN, Montreal, Canada. Filed Mar. 24, 1902. Serial No. 28,801. (No model.)

Claim.—1. In an undergarment, the combination, substantially as set forth, of a pair of sleeves having rear neck-flaps connected together and formed each with a breast-diagonal, a body having a back united to the lower edge of said rear neck-flaps and having a front with diagonal side margins adapted to underlie the breast-diagonals of the sleeves, and triangular gussets secured in the lower rear portions of the sleeves and to the back of the body.

2. In an undergarment, the combination, substantially as set forth, of a pair of sleeves having rear neck-flaps connected together and formed each with a breast-diagonal, a body having a back united to the lower edge of said rear neck-flaps and having a front with diagonal side margins adapted to underlie the breast-diagonals of the sleeves, and triangular gussets secured in the lower rear portions of the sleeves and to the back of the body, said breast-diagonals having lips formed at their bases and curved to the bases of the diagonal side margins of the front of the body.

3. In an undergarment, the combination, substantially as set forth, of a pair of sleeves having rear neck-flaps connected together and formed each with a breast-diagonal, a body having a back united to the lower edge of said rear neck-flaps and having a front with diagonal side margins adapted to underlie the breast-diagonals of the sleeves, triangular gussets connected in the inner rear portions of the sleeves and to the back of the body, and draw-strings secured to the upper extremities of the diagonal side margins of said body-front and adapted to adjust the distance between them.

4. In an undergarment, the combination, substantially as set forth, of a hip portion having a rear opening with separated vertical margins convexly curved toward each other, an inner flap having a convexly-curved margin secured to one of said first-mentioned margins, and an outer flap having a convexly-curved margin secured to the other one of said first-mentioned margins.

700,802. HEATING-FURNACE. HERBERT J. FOSTER, Ashland, Ohio. Filed July 23, 1901. Serial No. 69,574. (No model.)

Claim.—1. In a house-heating apparatus the combination of a combustion and heat-radiating chamber, consisting of a sheet-metal box A, a grate-frame D in the rear part of said box, a fireplace on said grate-frame, a fuel-receiving and coking chamber forward of said fireplace, a perforated draft-chamber over said coking-chamber, a vertical baffle-plate over said perforated chamber, and a head on the front beneath the smoke-pipe, and openings in the heater into said head, all constructed to operate substantially as described.

2. In a house-heating apparatus, a combustion and heat-radiating chamber consisting of a sheet-metal box A, a grate-frame D in the rear part of said box, a fireplace on the grate-frame, a fuel-receiving and coking chamber forward of said fireplace, a perforated draft-chamber over said coking-chamber, a vertical baffle-plate over said perforated chamber, and a head on the front beneath the smoke-pipe, in combination with the outer casing B the cold-air down-draft-pipe V, connected to lower end of said casing, and the hot-air-conducting pipes W connected to the doors of said casing, constructed to operate substantially as described.

700,808. PENCIL ATTACHMENT. ABRAHAM I. ORLANDY, Des Moines, Ia. Filed Aug. 9, 1901. Serial No. 71,948. (No model.)

Claim.—In a pencil attachment, the combination with the hollow cylinder A, formed with flange A', and longitudinal slot H; of the tube B, formed with the socket A and flange B', the back D, and the rod A', covering said back to the part B', of the said tube B; and said back and said tube adapted and arranged, to be placed in said hollow cylinder, with the flange B', resting on one of the flanges A', so

that said back can be rolled in and revolved out of said cylinder, through said slot H; substantially as shown and specified.

700,804. HAT-PIN RETAINER. GRANVILLE F. PARKER, Hampton, N. Y. Filed Nov. 14, 1901. Serial No. 52,168. (No model.)

Claim.—1. The combination in a hat-retainer of an eyelet having upon one end a flaring guiding-flange, and provided upon its other end with a screw-threaded shank; a nut fitting the said shank; a pin passing through said eyelet and said nut; and a spring arranged within the said nut, and normally projecting into the path of the said pin, substantially as described.

2. In a hat-retainer an eyelet consisting of a flaring guide-flange and tubular screw-threaded shank; a nut fitting the said shank; a hat-pin arranged in said eyelet; and a coiled spring arranged in said nut and projecting into the path of the said pin, and adapted by its tension to secure the said pin in position.

700,805. CAPSULE. GEORGE H. PARKER, Germantown, Pa. Assignor to Benjamin T. Abbott, Hyde, New York, N. Y. Filed Aug. 22, 1900. Serial No. 57,664. (No model.)

Claim.—1. A capsule, comprising an outer tube of compressible relatively tough material, an inner tube of gelatinous material, the inner tube adapted to contain a filler material and both tubes being flattened at their ends to insure the filler material.

2. A capsule, comprising an outer tube of compressible relatively tough material, an inner tube of gelatinous material, the inner tube adapted to contain a filler material and both tubes being flattened at their ends to insure the filler material, and the said tubes intermediate of their ends being flattened to form intermediate closures.

3. A capsule, comprising an outer tube of compressible but tough material, an inner tube of gelatinous material, the inner tube adapted to contain a filler material, the ends of the tubes being flattened to form closures and both tubes being flattened intermediate of their ends to form intermediate closures and points.

700,806. MANUFACTURE OF CAPSULES. GEORGE H. PARKER, Germantown, Pa. Assignor to Benjamin T. Abbott, Hyde, New York, N. Y. Original application filed Aug. 22, 1900. Serial No. 57,664. Revised and this application filed Oct. 9, 1901. Serial No. 71,957. (No model.)

Claim.—1. The method of making capsules, which consists first, in subjecting the interior of a tube of flexible and tough material to a gelatinous coating applied in a liquid or semifluid condition, and in then cooling and thereby hardening the interior coating.

2. The method of making capsules, which consists in first providing a tube of tough, flexible material, impermeable to the atmosphere, and in then hardening said tube by cooling the same.

3. The method of making capsules, which consists in forming a tube of tough, flexible material, then coating its interior with a gelatinous material applied in a liquid condition, then cooling and hardening the interior coating of said tube and finally subjecting the tube to heat prior to rolling the same under pressure.

700,807. MACHINE FOR MAKING IMPRESSIONS. GEORGE H. PARKER, Germantown, Pa. Assignor to Benjamin T. Abbott, Hyde, New York, N. Y. Filed Dec. 22, 1900. Serial No. 54,310. (No model.)

Claim.—1. A machine for the manufacture and printing of blanks involving a rotating impression-drum, a suitably-linked form-roller to bear on the periphery of said drum, device for feeding paper in a continuous strip forward, suitable mechanism for punching and shearing said continuous strip before reaching said drum, said punching and shearing mechanism being adjustable with relation to each other and to said drum, and means to convey operating power to said shearing and punching mechanism, substantially as shown and described.

2. In a machine of the class described consisting of an impression-drum, a suitably-linked printing-roller to convey impressions onto blanks passing around said drum, a paper-straightener adapted to receive the paper in a continuous strip from a roll and remove any bends therein, coiling-rolls to impress longitudinal indentations on said strip of material, a pair of feed-rollers adapted to be operated intermittently by means of a roller-clutch and punching and shearing device to operate on said strip of material, substantially as shown and described.

3. A machine for the manufacture and printing of blanks involving a rotating impression-drum, a suitably-linked form-roller to bear on the periphery of said drum, device for feeding paper in a continuous strip forward, suitable mechanism for punching and shearing said continuous strip before reaching said drum, said punching and shearing mechanism being adjustable with relation to each other and to said drum, and means to convey operating power to said shearing and punching mechanism, substantially as shown and described.

4. In a machine of the class described consisting of an impression-drum, a suitably-linked printing-roller to convey impressions onto blanks passing around said drum, a paper-straightener adapted to receive the paper in a continuous strip from a roll and remove any bends therein, coiling-rolls to impress longitudinal indentations on said strip of material, a pair of feed-rollers adapted to be operated intermittently by means of a roller-clutch, means to convey operating power to said shearing and punching mechanism, substantially as shown and described.

5. In a machine of the class described consisting of an impression-drum, a suitably-linked printing-roller adapted to make impressions upon blanks passing around said drum, a paper-straightener adapted to receive a strip of paper, a die-plate on said punch, sliding ways mounted on the under face of said die-plate, a depending integral strip on said die-plate, a plate bearing a series of punches to slide in said ways and abut against said depending strip, actuating device to rotate said last-mentioned plate freely against said strip, and a handle on said punch-bearing plate to remove the same when desired, substantially as shown and described.

6. In a machine of the class described consisting of an impression-drum, a suitably-linked printing-roller to convey impressions onto blanks passing around said drum, coiling-rolls to impress longitudinal indentations on an advancing strip of material, intermittently-operated feed-rolls to feed forward said strip, a reciprocating cross-head, a removable punch bearing a plate slidably attached to said cross-head to produce impressions of cuts on said strip of material, substantially as shown and described.

7. In a machine of the class described consisting of an impression-drum, a suitably-linked printing-roller to convey impressions onto blanks passing around said drum, a paper-straightener adapted to receive the paper in a continuous strip from a roll and remove any bends therein, coiling-rolls to impress longitudinal indentations on said strip of material, a pair of feed-rollers adapted to be operated intermittently by means of a roller-clutch, a series of dies to receive and contain said paper after leaving said rollers, punching mechanism to operate on said strip of material intermittently, dies to convey said strip from said punching device, a shearing device to cover said strip of material and a series of dies to convey and contain said material from said shearing device to said drum, substantially as shown and described.

8. A machine for the manufacture and printing of blanks involving a rotating impression-drum, a suitably-linked form-roller to bear on the periphery of said drum, device for feeding paper in a continuous strip forward, suitable mechanism for punching and shearing said continuous strip before reaching said drum, said punching and shearing mechanism being adjustable with relation to each other and to said drum, and means to convey operating power to said shearing and punching mechanism, a series of dies to receive the covered pieces of material between the shearing mechanism and the impression-drum, a number of spring-fingers adapted to press upon said material while on said dies during and immediately following said shearing operation, and a cam-operated arm to operate said spring-fingers, substantially as shown and described.

9. The combination in a machine for the manufacture and printing of blanks involving a rotating impression-drum, device for feeding paper in a continuous strip forward, two series of feeding-rolls for feeding forward a strip of material at a definite speed, one series whereof is capable of regulation as to speed, the other series being mounted on a shaft having an eccentric portion and capable of being rotated to cause a separation between said series, a lever adapted to rotate said upper shaft and cause such separation, substantially as shown and described.

10. The combination in a machine of the class designated, of rotating printing device, a frame to contain said printing device, horizontal brackets projecting from said frame, a housing for punching mechanism adjustably mounted on said brackets, a gear mounted in said housing, a main driving-shaft mounted in the frame of said machine, a gear mounted thereon, and an adjustable gear adapted to mesh with the gear of the main shaft and the gear in said housing whenever said housing is moved on said brackets, substantially as shown and described.

11. The combination in a machine for printing paper blanks for forms, of a rotating printing device, a frame to contain said printing device, horizontal brackets projecting from said frame, and an adjustable shear mechanism mounted on said brackets, a housing to contain said shear, a pair of rack-teeth on said shear, a transverse shaft mounted in the housing of said shear, pinions mounted on said transverse shaft to mesh in said rack-teeth, a crank mounted on the end of said transverse shaft, a longitudinally-adjustable connecting-rod attached to said crank and means to pass the rotation of said connecting-rod, substantially as shown and described.

700,808. ELECTRIC FURNACE. WILLIAM R. PARKER, Chicago, Ill. Filed July 23, 1901. Serial No. 69,585. (No model.)

Claim.—1. In an electric furnace the combination with a tubular positive electrode and gas-burning device extending through the walls of said electrode mediate its ends, of a suitable negative electrode.

2. In a furnace the combination with a tubular positive electrode having several terminals at its cooling end, and gas-burning device extending through the walls of said electrode mediate its ends, of a suitable negative electrode.

3. In an electric furnace the combination with a tubular positive electrode, and gas-burning device inserted through the walls and entering the base of the same, mediate its ends, of a negative electrode, and a drain therethrough for carrying off the molten products of the furnace.

4. In a furnace the combination with a tubular positive electrode, and gas-burning device inserted through the walls and into the base of the same mediate its ends, of a negative electrode having a gutter in its upper surface and a drain leading from said gutter.

5. In a furnace the combination with a tubular positive electrode, and gas-burning device inserted through the walls and into the base of the same mediate its ends, of a negative electrode having a chamber gutter concentric but greater in diameter than said positive electrode, and having a drain leading from said gutter.

6. In a furnace the combination with a tubular positive electrode having several terminals at its arcing end, and gas-burning devices inserted through the walls of and into the bore of the same, of a negative electrode having a drain therethrough.

7. In a furnace the combination with a tubular positive electrode having several terminals at its arcing end, and gas-burning devices inserted through the walls of and into the bore of the same, of a negative electrode having a gutter in its upper surface, and a drain leading from said gutter.

8. In a furnace the combination with a tubular positive electrode having several terminals at its arcing end, and gas-burning devices inserted through the walls of and into the bore of the same, of a negative electrode having a circular gutter and its upper surface concentric to but greater in diameter than said positive electrode.

9. In a furnace the combination with a longitudinally-adjustable tubular positive electrode having several terminals at its arcing end, and gas-burning devices inserted through the walls of and into the bore of the same, of a negative electrode having a drain therethrough.

10. In a furnace the combination with a longitudinally-adjustable tubular positive electrode having several terminals at its arcing end, and gas-burning devices inserted through the walls of and into the bore of the same, of a negative electrode having a gutter in its upper surface, and a drain leading from said gutter.

11. In a furnace the combination with a longitudinally-adjustable tubular positive electrode having several terminals at its end, and gas-burning devices inserted through the walls of and into the bore of the same, of a negative electrode having a circular gutter and its upper surface concentric to but greater in diameter than said positive electrode.

700,809. MEANS FOR EXTINGUISHING ARCS IN ELECTRICAL APPARATUS. HERALD W. CARTER, London, England. Filed Mar. 28, 1901. Serial No. 85,094. (No model.)

Claim.—1. The combination with an electric circuit designed to carry current of considerable tension and between parts of which an electric arc of destructive dimension is liable to be set up, of a self-contained blow-out device arranged external to the parts between which an electric arc is liable to be set up and adapted to be automatically brought into action by the heat of an arc of undue dimension and to blow out such arc.

2. The combination with an electric circuit designed to carry current of considerable tension and between parts of which an electric arc of destructive dimension is liable to be set up, of a self-contained blow-out device arranged external to the parts between which an electric arc is liable to be set up and comprising a vessel charged with blast-producing material and arranged to have its contents liberated as a jet or blast by the action of the heat of an arc of undue dimension.

3. The combination with an electric circuit designed to carry current of considerable tension and between parts of which an electric arc of destructive dimension is liable to be set up, of a blow-out device comprising a vessel containing an explosive charge and having a normally

closed fusible end arranged to be opened by the heat of an arc of undue dimension and partial of the sudden liberation of a jet or blast from said vessel.

4. The combination with an electric circuit designed to carry current of considerable tension and between parts of which an electric arc of destructive dimension is liable to be set up, of a blow-out device comprising a vessel charged with fluid under pressure and having a normally closed fusible end arranged to be melted by the action of an arc of undue dimension and to cause the issuing jet or blast of fluid to blow out the arc.

5. The combination with an electric circuit designed to carry current of considerable tension and between parts of which an electric arc of destructive dimension is liable to be set up, of a blow-out device arranged external to the parts between which an electric arc is liable to be set up and comprising a conducting vessel that is in electrical connection with such circuit and contains a blast-producing charge adapted to be liberated as a jet or blast by the action of an arc of undue dimension, and in blow out such arc.

6. The combination with an electric fuse, of a self-contained blow-out device arranged external to the parts between which an electric arc is liable to be set up and adapted upon the melting of the fuse conductor or conductors and the setting up of an arc of undue dimension, to be brought into action to discharge a jet or blast of fluid against such arc.

7. In an electric fuse, the combination with the fusible conductor or conductors therein, of a self-contained blow-out device arranged external to the parts between which an electric arc is liable to be set up and comprising a closed vessel containing an explosive charge and arranged to be opened and its contents liberated in the form of a jet or blast by the heat of an arc of undue dimension set up by the melting of the fusible conductor or conductors.

8. In an electric fuse, the combination with the fusible conductor or conductors therein, of a blow-out device comprising a metal vessel containing an explosive charge, said vessel being in electrical connection with one end of said fusible conductor or conductors and arranged to be heated and its contents liberated in the form of a jet or blast by an arc of undue dimension set up by the melting of the said fusible conductor or conductors.

9. In an electric fuse, the combination with a fusible conductor or conductors of self-contained blow-out device comprising closed vessels containing, in themselves an explosive charge, arranged at or near the opposite ends of the fusible conductor or conductors, and adapted to be opened and their contents liberated by the heat of an arc of undue dimension set up by the melting of the fusible conductor or conductors.

10. In an electric fuse, the combination with a fusible conductor or conductors of blow-out device comprising vessels having an explosive charge, arranged at or near the opposite ends of the fusible conductor or conductors, and adapted to be opened and their contents liberated by the heat of an arc of undue dimension set up by the melting of the fusible conductor or conductors, said vessels being each in electrical connection with said fusible conductor or conductors.

11. In an electric fuse, the combination with a fusible conductor or conductors of blow-out device comprising vessels charged with compressed fluid and having fusible ends the ends arranged in proximity to the ends of said fusible conductor or conductors, substantially as described for the purpose specified.

700,810. CARTRIDGE. EDGAR FERRISS, New York, N. Y. Filed July 18, 1901. Serial No. 86,000. (No model.)

Claim.—1. In a cartridge, the combination with a side frame, comprising

prising pedestal, a beam connecting such pedestals together at or about their vertical centers, and extension-beams, and under trans-beams connected to the pedestals and supporting said end extension-beams, each of the said end extension-beams being provided with a socket upon its upper surface; of a top chord or rail, provided with a socket on its under side; a partial elliptic spring the rear end of which is secured in the socket on the end extension-beam and the front end of which is inserted in the socket on the top chord or rail; and brackets or stops projecting upwardly from said end extension-beam and downwardly from said top chord or rail, and adapted to engage and calipers to prevent longitudinal motion of said top chord or rail with reference to said side frame.

2. In a car-truck, the combination with a side frame comprising pedestals, beams 11 and 12 connecting the pedestals together, and extension-beams, and under trans-beams connected to the pedestals and supporting said end extension-beams; of a top chord or rail; partial elliptic springs actuated on said end extension-beams near the points of attachment of the under trans-beams to the end extension-beams; sockets on the top chord adapted to receive the extended front ends of the said partial elliptic springs and sockets on the said end extension-beams adapted to receive the rear ends of the said partial elliptic springs, whereby the strain of the load at the ends of the truck is transmitted through said springs, under trans-beams and lower horizontal connecting beams 13, thus relieving a substantial trans extending beyond the normal ends of the truck frame; and brackets or stops projecting upwardly from said end extension-beams and downwardly from said top chord or rail, and adapted to engage and calipers to prevent longitudinal motion of said top chord or rail with reference to said side frame.

3. In a car-truck, the combination with the top chord or rail and the end beam, of a leaf or partial elliptic spring mounted on the end beam, a socket also mounted on the end beam and receiving the rear horizontal portion of said spring and provided with a groove in its face above the spring, and a bracket secured to the rail and having a depending portion adapted to slide in the groove of said socket, the front end of said spring being curved in elliptic form and extending outward and suitably connected to the rail.

4. The combination with the top chord or rail and the extended end beam, of a partial elliptic spring actuated on the end beam, a socket on the end beam to receive the rear portion of said spring and provided with a groove in its vertical face, a bracket secured to the rail and having a depending portion which slides in the groove of said socket and a socket attached to the top chord to receive the extended front end of the partial elliptic spring and which is adapted to slide in said socket, substantially as set forth.

5. In a car-truck, a beam for supporting the rear of the same having a strap or casting 20 riveted thereto and provided with an opening

coinciding with the opening in the beam, whereby said beam is reinforced and an elongated bearing for the rear of the motor is provided.

6. The combination with the side beams of the truck frame and cross-beam 20 rigidly secured in pockets to said side beams, of a pair of brackets secured to said cross-beam, and a motor-suspension bar 25 spring-supported on said brackets and having riveted thereto the plate or casting 30 having an elongated opening coinciding with the opening in the bar 20, substantially as set forth.

700,811. SWITCH AND FROG. JAMES S. PENNY, Baltimore, Md., assignor, by mesne assignments, to Burlington O. Road, Carter Road, N. H. Filed Aug. 20, 1901. Serial No. 73,546. (No model.)

Claim.—1. In a railway frog and switch, the combination of the usual fly-rails; the fixed frog-point B; the movable lower rail A, A' bent outwardly at an angle to fit the sides of the point when shifted from side to side; a sleeve d' between said rails to hold them properly spaced; a bolt d through said sleeve; hollow studs on the sides of the rail through which said bolt d extends; caps on the studs; springs within the caps for holding the rails with a strong pressure against the sleeve d'; a yoke D under the rails at the angle of the same; studs E bolted to the outside of said rail opposite said yoke; caps F to reciprocate over said studs with springs within the same; flanges E' secured to said caps; bolts a through said caps into the studs E; toggle-joints connected to the yoke at each side and to bars F secured to the ties within the outer rails; rods H, H, connected to said toggles; bell-crank levers connected to said rods H coupled together by a suitable rod; and connections therefrom to the switch-stand, all operating, substantially as described for the purpose specified.

2. In a railway frog and switch, the combination of the usual fly-rails; the fixed frog-point B; the movable lower rail A, A' bent outwardly at an angle to fit the sides of the point when shifted from side to side; a sleeve d' between said rails to hold them properly spaced; a bolt d through said sleeve; hollow studs on the sides of the rail through which said bolt d extends; caps on the studs; springs within the caps for holding the rails with a strong pressure against the sleeve d'; a yoke D under the rails at the angle of the same; studs E bolted to the outside of said rail opposite said yoke; caps F to reciprocate over said studs with springs within the same; flanges E' secured to said caps; bolts a through said caps into the studs E; suitable connections to said yoke from the switch-stand to shift the same from side to side for the purpose specified.

3. In a railway frog and switch the combination of a fixed frog-point; movable rails to each side thereof bent at an angle corresponding to said point, adapted to fit either side; a spacer between said rails to hold them apart; a yoke extending beneath the rails with spring-pressure device to permit the rails to yield outwardly; suitable guides for the ends of the rails; a toggle-joint at each end of the yoke; and suitable connections from said toggle-joints to the switch-stand to throw the rails from side to side and lock the same in position, for the purpose specified.

4. In a railway frog and switch, the combination of a fixed frog-

point; movable rolls to each side thereof; a yoke for the rolls with spring engagement to the side of the rolls to permit them to yield laterally outward; a toggle-joint at each end of the yoke; and suitable connections from said toggle-joints to the switch-stand to throw the rolls from side to side, for the purpose specified.

5. In a railway flag or switch, the combination of a fixed frog-point; movable rolls to each side bent at an angle corresponding to said frog; a yoke for the rolls; toggle-joints at each end of said yoke with connections for actuating the same, for the purpose specified.

700,812. ELECTRIC ALARM. GUY M. PETER, Oak Lake City, Wash. Filed June 1, 1901. Serial No. 62,734. (No model.)

Claim.—1. In a circuit-closer the combination of a stationary casing, electric circuits arranged within the casing, an armature pivotedly mounted in the casing, a spring mounted on the armature to normally hold it in contact and thereby close the circuit, a movable member, a magnet therein with which the armature contacts to hold the circuit open in normal position when the magnet is engaged with the armature and whereby the circuit is closed when the magnet and movable member are moved away from the armature.

2. A burglar-alarm comprising a stationary member and a movable member, in combination with a magnet secured to the movable member, an armature and electric connections secured to the other member, said magnet attracting the armature to hold the circuit open, a spring for retracting the armature to close the circuit when the magnet is moved from the armature, and a screw bearing on the end of said spring to regulate the tension thereof.

3. In a burglar-alarm, the combination with a window-frame having a recess therein, of electric circuits arranged therein, an armature pivotedly mounted in said recess, means to normally hold the armature in contact, a window-latch having a recess, and a magnet located therein with which the armature contacts to hold the circuit open.

4. In a burglar-alarm, the combination with a window-frame carrying an armature and electric-circuit connection, a window-latch carrying a magnet with which the armature contacts to hold the circuit normally open in one position of said frame, and a spring for retracting the armature to close the circuit when the magnet is moved out of engagement therewith.

700,813. STAIR-ROUTING MACHINE. FRANK V. PHILLIPS, Waukegan, Ill., assignor to the Smith and Phillips Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Nov. 7, 1900. Serial No. 24,728. (No model.)

Claim.—1. The combination with a stationary table, the work-supporting rollers 20 and 21, and a cutter movable vertically upward through the table, the rollers being arranged in alignment with the cutter and with each other, of the pattern-frame adapted to be secured to the upper surface of the stringer and means for guiding the movements of the stringer in accordance with the pattern, substantially as specified.

2. The combination with the table of a stair-cutting machine of rollers 20 and 21, the ring 22, and posts 23, substantially as specified.

3. The combination with the table and cutter of a stair-cutting machine of rollers 20 and 21 at opposite sides of the cutter, a ring 22 surrounding the cutter, and posts 23, the rollers being journaled in the ring and posts, substantially as specified.

4. The combination with the table and cutter of the stair-cutting machine, of rollers 20 and 21 journaled in removable supports and supporting the stringer, the rollers being independent of each other and located in alignment with the cutter and with each other and at opposite sides of the cutter, substantially as specified.

5. The combination with the table and cutter of a stair-cutting machine of the work-supporting rollers 20 and 21, and the ring 22 secured to the table around the outer opening and carrying both to intercept the shavings and as a support to said rollers, substantially as specified.

6. The pattern-frame for stair-routing consisting of two L-shaped pieces, one of which is provided with right-angled projections at its extremities to which the other piece is joined by bolts passing through elongated slots and by which means the pieces are rigidly held in their relative positions; substantially as specified.

7. The combination with the table and cutter, of removable rollers for supporting the sheet, a removable ring encircling the cutter and supporting the rollers at their inner ends, and removable posts supporting the outer ends of the rollers, substantially as specified.

700,814. SAFE-BALANCE. GEORGE A. FRANK and WILLIAM R. COOPER, New Britain, Conn., assignors to F. & P. Curtis, New Britain, Conn., a Corporation of Connecticut. Filed Feb. 27, 1902. Serial No. 35,092. (No model.)

Claim.—1. In a device of the character described, a platen, a spring anchored at one end and secured at its other end to said platen or an extension thereof, a second platen concentric with the first-mentioned platen and another spring, said second spring being anchored at one end and secured at its other end to said second platen or an extension thereof, and means to engage and disengage said platens.

2. In a device of the character described, a platen, a spring anchored at one end and secured at its other end to said platen or an extension thereof, a second platen concentric with the first-mentioned platen and another spring, said second spring being anchored at one end and secured at its other end to said second platen or an extension thereof, means to

engage and disengage said platens, and means to lock said platens against rotation.

3. In a device of the character described, a platen, a spring anchored at one end and secured at its other end to said platen or an extension thereof, a second platen and another spring, said second spring being anchored at one end and secured at its other end to said second platen or an extension thereof, and a clutch device carried by each of said platens one of said clutch devices being movable laterally of said platens to engage or disengage the other clutch device.

4. In a device of the character described, a platen, a spring anchored at one end and secured at its other end to said platen or an extension thereof, a second platen and another spring, said second spring being anchored at one end and secured at its other end to said second platen or an extension thereof, and a clutch device carried by each of said platens one of said clutch devices being movable laterally of said platens to engage or disengage the other clutch device, a locking-clutch carried by said movable clutch device and a stationary member adjacent said locking-clutch adapted to receive and hold the latter against rotation.

5. In a device of the character described, a pair of platens, a shaft extending from one and a drive extending from the other and surrounding said shaft, a second drive mounted on the end of said shaft and free to shift longitudinally thereon but not to rotate independently thereof, clutch-teeth at the adjacent ends of said drives, means to shift said second drive, and means to lock said second drive and thereby both of said platens when said teeth and locking means are in disengaged operative engagement.

6. In a device of the character described, a pair of platens, a shaft extending from one and a drive extending from the other and bearing upon said shaft, a second drive on that portion of said shaft extending beyond said first drive, said second drive being longitudinally but not rotatably mounted relatively to said shaft, long clutch-teeth at the adjacent ends of said drives and short clutch-teeth on another portion of said second drive, and a stationary member bearing short teeth to mesh with said short teeth on said second drive to lock all of said parts when both of said drives are interlocked.

7. In a device of the character described, a pair of platens, a shaft extending from one and a drive extending from the other and bearing upon said shaft, a second drive on that portion of said shaft extending beyond said first drive, said second drive being longitudinally but not rotatably mounted relatively to said shaft, long clutch-teeth at the adjacent ends of said drives and short clutch-teeth on another portion of said second drive, and a stationary member bearing short teeth to mesh with said short teeth on said second drive to lock all of said parts when both of said drives are interlocked.

8. In a device of the character described, a pair of platens, means for interlocking the same, said means including a reversible member, a circular rotatable rack carried thereby and a platen in mesh therewith, the axis of said rack being at an angle to the axis of said platen.

9. In a device of the character described, a pair of platens, means for interlocking the same and locking said interlocked platens with a stationary part, springs connected with said platens and with a suitable stationary part, and a wall in mesh with each of said platens and windows carrying said racks.

10. In a device of the character described, a pair of toothed platens, a rack for each of said platens, a clearance-space between said platens about equal to the thickness of one of said racks.

11. In a device of the character described, a pair of toothed platens, a rack for each of said platens, a clearance-space between said platens about equal to the thickness of one of said racks, and interlocking means for said platens.

700,815. DEVICE FOR SUPPORTING AND DELIVERING PAPER FOR WRAPPING OR BINDING PURPOSES. ROBERT H. PETER, Oak Lake City, Wash., assignor, by direct and mesne assignments, to National Specialty Manufacturing Co., Jersey City, N. J. Filed Aug. 1, 1901. Serial No. 24,028. (No model.)

Claim.—1. In an apparatus for supporting and delivering paper for wrapping or binding purposes, the combination with the holder for a roll

of paper, and a maintaining device, of a feed-guide for directing the paper to the maintaining device comprising a swinging guide-plate having side flanges near its delivery end, a transverse rod upon which said plate is suspended, and a counterweight, substantially as set forth.

2. In an apparatus for supporting paper for wrapping or binding purposes arranged to deliver independent strips of paper, the combination of the roll-holder for the strips of paper, a maintaining device, a counter-weight, a plurality of independent movable paper-feed guides, one for each strip of paper, arranged on a single shaft, and independent controlling means, one for each paper-guide arranged to normally hold the delivery end of the guide away from the maintaining device, substantially as set forth.

700,816. DEVICE FOR SUPPORTING AND DELIVERING PAPER FOR WRAPPING OR BINDING PURPOSES. ROBERT H. PETER, Oak Lake City, Wash., assignor, by direct and mesne assignments, to National Specialty Manufacturing Co., Jersey City, N. J. Filed Apr. 1, 1901. Serial No. 24,028. (No model.)

Claim.—1. The combination of a holder for a roll of paper, a device for maintaining the surface of the paper, and a swinging frame over which the paper passes arranged normally to hold the paper away from the maintaining device, and to yield to allow the paper to engage there-with when the paper is drawn off the roll, substantially as set forth.

2. The combination of a holder for a roll of paper, a device for maintaining the surface of the paper, and a device which automatically moves the paper away from the maintaining device, arranged between the paper-holder and the maintaining device, substantially as set forth.

3. The combination with a holder for paper and a device for maintaining the surface of the paper, of a frame pivoted between its ends and having one end weighted and the other end arranged to support the paper and normally hold it away from the maintaining device, substantially as set forth.

4. The combination of a support for a roll of paper, a water-holder, a maintaining-roller mounted therein, and a knife arranged to sever the paper after it has passed beyond the maintaining-roller, the cutting edge of the knife when in position to sever the paper acting against the inner edge of the front wall of the water-holder, whereby when the knife severs the paper it leaves the end of the main body of paper projecting slightly beyond the maintaining-roller and in proximity thereof, substantially as set forth.

5. The combination of a support for a roll of paper, a roller for maintaining the surface of the paper, a knife for severing the paper adjacent to the said roller, and means for moving the free end of the paper which is adjacent to the surface of the maintaining-roller away therefrom, substantially as set forth.

6. The combination of a holder for a roll of paper, a maintaining-roller, a movable frame over which the paper passes arranged on one side of the maintaining-roller and arranged to normally hold the paper from contact with said roller, and a knife for covering the paper arranged on the side of the maintaining-roller opposite the said movable frame, substantially as set forth.

7. The combination of a support for a roll of paper, a water-holder, the rollers M, L, mounted in the water-holder, a weighted swinging frame over which the paper passes arranged to hold the paper away from the roller M, and the knife arranged to cover the paper on the side of the roller L opposite to the said swinging frame, substantially as set forth.

700,817. SUGAR-GRATE. JOHN C. FORTNEY, Columbus, Ohio. Filed May 12, 1902. Serial No. 62,522. (No model.)

Claim.—In a sugar-grate, the combination of a floor-section, side and end sections hinged thereto, said side and end sections each consisting of a frame enclosing a plurality of vertically-arranged slots, transverse rods extending said slots and the alternate slots formed with the openings 11 and means for detachably connecting said side and end sections, catch-plates 12 on one of said side sections and a strap 22 on the opposite section, upright catch-bars 23 affixed to a vertical side extension of the floor-section, a strap 27 projecting from the opposite vertical side extension of the floor-section, a key 13, lock-bars 14 on one side thereof and a hinged lever 15 depending from the opposite side, substantially as specified.

700,817.

700,818. BRAKE MECHANISM FOR RAILWAY-CARR. GEORGE W. FOWELL, Green Island, N. Y. Original application filed Feb. 9, 1901. Serial No. 44,954. Divided and this application filed Oct. 2, 1901. See also No. 77,904. (No model.)

Claim.—1. In a brake mechanism for vehicles, the combination with the truck-frame and a pair of wheels provided with bearings in said frame; of brake-chess engageable with said wheels respectively; a shoe-supporting brake-beam movably supported on said frame; a pair of levers pivoted at their outer ends upon the outer ends of said brake-beam and having their inner ends pivotally connected together, and their intermediate portions connected with a rotating medium; a brake-operating lever pivoted at one end to the middle of the brake-beam; and a link connecting said operating-lever with one of the levers of said pair, substantially as described.

2. In a brake mechanism for vehicles, the combination with the truck-frame; and axles and wheels provided with bearings in said frame; of brake mechanism at each end of the truck comprising brake-chess engageable with the wheels at each end respectively; a shoe-supporting brake-beam movably supported on said frame; a pair of levers pivoted at their outer ends upon the outer ends of said brake-beam and having their inner ends pivotally connected together; a brake-operating lever pivoted at one end to the middle of the brake-beam; and a link connecting said operating-lever with one of the levers of said pair; and links connecting each of the levers of said pair with its corresponding lever on the same side at the opposite end of the truck, substantially as described.

700,819. ACETYLENE-GAS GENERATOR. JOHN GUNY and JAMES A. RAIN, Cleveland, Ohio. Filed Sept. 5, 1901. Serial No. 74,369. (No model.)

Claim.—1. In an acetylene-gas apparatus, the combination with a generator, a condensing-chamber thereunder, and generator, of a pipe leading from the generator to the condensing-chamber, said pipe having connection with the generator at both the top and bottom thereof forming gas and water passages therefrom.

2. In an acetylene-gas apparatus, in combination, a generator, a gas-generator, a condensing-chamber, a washing device in the condensing-chamber comprising a receptacle open at the bottom the lower edge of which extends below the water-level in the condensing-chamber, a pipe from the generator entering the receptacle below the water-level, connection between the pipe and the generator at both the bottom and the top thereof, whereby the pipe acts both as a gas-pipe and a drain-pipe for the generator, and a pipe communicating from the receptacle to the generator.

3. In an acetylene-gas apparatus, the combination with a generator, a valved water-feed pipe therefor, and a rising-and-filling gasometer, of a rod connected to the gasometer to rise and fall therewith and to the valve of the water-pipe to operate the same, said rod having a twisted portion to open the valve and portions above and below the twisted portion to close the valve.

4. In an acetylene-gas apparatus, in combination, a rising-and-filling gasometer, a gas-generator, a water-supply pipe therefor, a rod connected to the gasometer, a spiral projection on the rod, a lever having sliding engagement with the spiral and adapted to be operated thereby according to the rise and fall of the rod, a valve in the water-supply pipe, and connections between the lever and the valve to open and close the valve.

5. In an acetylene-gas apparatus, in combination, a rising-and-filling gasometer, a gas-generator connected thereto, a water-supply pipe for the generator, a valve in the pipe, a revolvable slotted plate, a twisted rod connected to the gasometer and adapted to rise and fall therewith, said rod extending through the slot in the plate and being adapted to turn the plate by engagement of the twist with the slot, connections between the plate and the valve whereby a movement of the plate operatively opens and closes the valve according to the fall and rise of the gasometer.

6. In an acetylene-gas apparatus, in combination, a gasometer adapted to rise and fall, a gas-generator, a water-supply pipe therefor, a valve in said pipe, a pivoted cylinder on an arm projecting from the cylinder and connected to the valve, a cap on the upper end of the cylinder having a slot, a twisted rod extending through said slot and connected to the gasometer to rise and fall with the same, whereby the twist of the rod passing through the slot will cause the cylinder to turn on its pivot and to open or close the valve.

700,820. TREE-PROTECTOR. ALLEN RALSTON, Nashville, Tenn. Filed Feb. 10, 1902. Serial No. 93,363. (No model.)

Claim.—A tree-protector comprising a flexible body portion, rods connected to the upper and lower edges of the body portion, and said rods

mounted to the body portion intermediate its upper and lower edges, each of said rods projecting beyond the ends of the body portion and formed with eyes, and rods engaged with the eyes of said rods and each having angularly-projected registering eyes, vertical stakes secured to the upper and lower rods and having their lower ends projecting below the lower edge of the body portion, and a removable driving-stake adapted to be inserted through the angularly-disposed eyes and with the first-named driving-stake to be driven in the ground and then anchor the body portion in position around the tree-trunk, substantially as and for the purpose specified.

700,821. APPARATUS FOR TRANSPLANTING TREES. DAVID RALSTON, Altonhurst, N. J., assignor of two-thirds to J. M. Ralston and E. H. Ralston, Altonhurst, N. J. Filed Jan. 7, 1901. Serial No. 62,418. (No model.)

Claim.—1. A transplanting comprising a frame, a drum, a shaft in rear of the drum, chains adapted at one end for attachment to a tree and secured at the rear end to said shaft, the intermediate portions of the chains passing over the drum to rotate it, and a ratchet device for rotating said shaft to wind the chains thereon, turn the drum and pull the tree over the same.

2. A transplanting comprising a frame, a drum revolvably mounted thereon, a shaft revolvably mounted on the frame in rear of the drum, a ratchet-wheel secured on said shaft, a lever, a dog connected to the lever for rotating the ratchet-wheel when the lever is operated, a pawl adapted to engage the ratchet-wheel and prevent return thereof, pulleys rigid with the ends of said drum, chains secured to the shaft and passing over the said pulleys to rotate the drum and hook on the ends of the chains adapted to be joined together beneath the roots of a tree.

3. A transplanting comprising a frame, a drum revolvably supported at one end of the frame, a shaft revolvably supported on the frame in rear of the drum, grooved pulleys secured to the ends of the drum, chains secured to the shaft and passing over the pulleys to rotate the drum and simultaneously pull a tree over the same, hooks on the ends of the chains adapted to be joined together beneath the roots of a tree, and ratchet-blocks, each having a series of notches for the reception of a crowbar, on the shaft.

4. In an apparatus for transplanting trees, the combination with a body mounted on wheels, of standards secured to said body near one end thereof, a shaft supported in said standards and projecting beyond the same at both ends, a drum secured on said shaft between the standards, grooved pulleys secured to rotate with the drum, another shaft revolvably supported on said body in rear of the first-mentioned shaft, chains secured to said last-mentioned shaft and passing over the pulleys so as to rotate the drum and simultaneously pull a tree over the same, said chains being adapted to be attached to a tree, means for rotating said shaft, and ratchet-blocks, each having a series of notches for the reception of a crowbar for attachment to either of said shafts for governing the speed of rotation of said shafts.

5. In a transplanting, the combination with a frame, of a drum mounted thereon provided with rigid pulleys, a shaft in rear of the drum, chains wound on said shaft and passing over said pulleys so as to rotate the drum and pull a tree over the same when the shaft is rotated and ratchet-blocks located on the shaft in rear of the drum and each block having recesses for the reception of a crowbar, substantially as and for the purpose herein set forth.

700,822. HAY-THRESHING MACHINE. CHARLES E. BARNES, Barnbury, Conn. Filed Sept. 2, 1901. Serial No. 74,542. (No model.)

Claim.—1. The combination of a frame, a hat-support, means for rotating said hat-support, a horizontal series of levers supported by and having a vertical pivot on the frame whereby they are enabled to swing in a horizontal plane, a device for operating on a hat on the support, carried by the outer of said levers, and movable in a horizontal plane forwardly at one side of the hat-support, across the tip of the support and rearwardly at the opposite side of the support, means for holding the said device to the hat on the support, and means for swinging the levers on the vertical pivot and in a horizontal plane.

rearwardly at the opposite side of the support, means for holding the said device to the hat on the support, and means for swinging the levers on the vertical pivot and in a horizontal plane.

2. The combination of a frame, a hat-support, means for rotating the support, a horizontal series of levers supported by and having a vertical pivot on the frame whereby they are enabled to swing in a horizontal plane, a horizontally-disposed roller carried by the outer of said levers, and movable in a horizontal plane forwardly at one side of the hat-support, across the tip of the support, and rearwardly at the opposite side of the support, and means for swinging the levers on the vertical pivot and in a horizontal plane.

3. The combination of a frame, a hat-support, means for rotating the support, a horizontal series of levers supported by and having a vertical pivot on the frame whereby they are enabled to swing in a horizontal plane, a horizontally-disposed roller carried by the outer of said levers, and movable in a horizontal plane forwardly at one side of the hat-support, across the tip of the support, and rearwardly at the opposite side of the support, means for swinging the levers on the vertical pivot and in a horizontal plane, and means for yieldingly pressing the roller against the hat on the support incident to its movement around the same.

4. The combination of a frame, a hat-support, means for rotating the support, a horizontal series of levers supported by and having a vertical pivot on the frame, an upright spindle pivoted on the outer of the levers so as to rest on its axis, a horizontally-disposed roller mounted in said upright and movable through the medium of the levers in a horizontal plane forwardly at one side of the hat-support, across the tip of the support, and rearwardly at the opposite side of the support, means for swinging the levers on the vertical pivot and in a horizontal plane, and a weight connected with the spindle-support of the roller for yieldingly pressing the roller against a hat on the support.

5. The combination of a frame, a hat-support, means for rotating the support, a horizontal series of levers supported by and having an upright, tubular pivot journaled in the frame, one or more sheaves on the inner portion of the lower lever, an upright spindle pivoted on the outer of the levers so as to rest on its axis, a horizontally-disposed roller mounted in said upright and movable through the levers in a horizontal plane around the support, means for swinging the levers in a horizontal plane on their pivot, a cord connected to the spindle supporting the roller and passed around the sheave or sheaves and down through the tubular pivot, and a weight on said cord.

6. The combination of a cone-shaped hat-support, means for rotating the same, and a roller for pressing against a hat-support; said roller being made up of sections rotatable independent of each other.

7. The combination of a cone-shaped hat-support, means for rotating the same, a horizontally-disposed roller arranged to press against a hat on the support and comprising a plurality of sections rotatable independent of each other, means for moving said roller in a horizontal plane forwardly at one side of the support, across the tip of the same, and rearwardly at the opposite side of the support, and means for yieldingly pressing the roller against a hat on the support incident to each movement.

700,823. BRICK-PRESS. CHARLES W. RETHMAN, Toledo, Ohio, assignor of one-half to Louis T. Penney, Toledo, Ohio. Filed Sept. 12, 1901. Serial No. 74,543. (No model.)

Claim.—1. In a brick-press, the combination of a platform or supporting-frame, a head-block supported above said platform, fastening-bolts inserted through the head-block and the platform, a resistance-plate on the lower ends of the bolts, springs coiled around the bolts between the platform and the resistance-plate, a mold-wheel arranged below the head-block, and means for pressing a brick in the mold-wheel against the head-block.

2. The combination of a rotary mold-wheel, means for forming and pressing a brick therein, a rake arranged above the mold-wheel to remove the finished brick, a lever connected with and adapted to rotate the rake, a tappet-disk having a pin adapted to impinge against the lower end of said lever, and means for operating the tappet-disk.

3. In a brick-press, the combination of a rotary mold-wheel, a head-

block above the same, a vertically-movable mold-bottom in the mold-wheel, means for raising said mold-bottom, and a movable plate in the lead-block adapted to receive the pressure of the raised mold-bottom.

4. The combination of a rotary mold-wheel, vertically-movable mold-bottom therein, a plunger adapted to raise a mold-bottom to press a brick, a second plunger adapted to further raise the mold-bottom, means for operating the said plungers, and a supporting-plate between the plungers to prevent dropping of the mold-bottom.

5. In a brick-press, the combination of a rotary mold-wheel, a slide below the same, a vertically-movable plunger mounted in the slide and adapted to act on the movable mold-bottom in the mold-wheel, a cam fitted in said plunger, and means for raising said cam.

6. The combination of the mold-wheel having an annular rack on its outer side, a driving-shaft carrying a pinion meshing with said annular rack, a compressing-plunger, a cam on the end of the driving-shaft fitted in said plunger, an expelling-plunger, a shaft having a cam fitted in said plunger, and a pinion on said shaft meshing with the annular rack-bar on the mold-wheel.

7. The combination of the mold-wheel having mold-cavities provided with guiding-ribs on their walls and with steps near their lower ends, and movable mold-bottoms fitted loosely in the mold-cavities having notches engaging the ribs and shoulders engaging said steps.

700,824. SECTIONAL GAS-RETORT. GEORGE F. KEMPER, Station, Germany. Filed Mar. 12, 1901. Serial No. 91,996. (No model.)

Claim.—1. A retort divided transversely into sections, the end of each section formed by planes at an angle to the axis of the retort, and offset between the planes to form locking members, substantially as described.

2. A retort divided transversely into sections, the end of each section formed by parallel planes cutting the axis of the retort, an angle to form two abutting flanges and an offset between the two flanges, substantially as described.

3. A retort divided transversely into sections, the end of each section formed by parallel planes cutting the axis of the retort, and an offset between the planes at about its medial line, substantially as described.

4. A retort divided transversely into sections, the end of each section formed by two pairs of parallel planes, said pairs of planes at an angle to each other and to the axis of the retort, and an offset between the planes of a pair, substantially as described.

5. A retort divided transversely into sections, the end of each section formed by two pairs of parallel planes, cutting the retort to its vertical medial line, said pairs of planes at an angle to each other and to the axis of the retort, and an offset between the planes of a pair at about the lateral medial line, substantially as described.

700,825. TOOL FOR FINISHING METAL SURFACES OR THE LIKE. SAMUEL LITTELL, JR., Philadelphia, Pa., assignor to W. A. Newman, Portland, Philadelphia, Pa. Filed Feb. 12, 1901. Serial No. 65,891. (No model.)

Claim.—1. In a tool of the character described, a support, a curved or arc-shaped head provided on its inner face with cutting or scraping edges and normally arranged concentric with the periphery of the support, means for flexibly connecting one end of the tool to the periphery of the support so as to permit the tool to swing concentrically to the support and resilient means interposed between the inner face of the tool and the support.

2. In a tool of the character described, a scraping-tool comprising a curved plate provided on its outer face with scraping edges, a central support, a resilient means interposed between the plate and the support, and a link for connecting one end of said plate to said support and thereby permitting the plate to swing concentrically toward or away from the periphery of the support.

700,826. WATER-PURIFYING APPARATUS. JAMES BOAR, Portsmouth, Va. Filed Feb. 12, 1901. Serial No. 92,728. (No model.)

Claim.—1. In a water-purifying apparatus a settling-compartment provided with a valve-controlled outlet and a series of baffles-plates whereby the water is caused to travel the length of the compartment in a tortuous path, and with an overflow-opening which extends practically the length of the compartment and is located above the normal level of the water therein, substantially as and for the purposes hereinbefore set forth.

2. A water-purifying apparatus consisting of a settling-compartment, a filter-compartment and a purified-water receptacle or compartment, communicating one with the other in the order named, an inlet-pipe leading the water to be purified into the settling-compartment, an outlet-pipe for leading off the purified water from the purified-water receptacle, valves for controlling the flow of water through the several compartments and an overflow-opening formed in and extending practically the length of the settling-compartment at a point above the normal level of the water therein, substantially as and for the purposes hereinbefore set forth.

3. A water-purifying apparatus composed of a tank having a removable cover and divided lengthwise by cross-partitions into a settling-compartment, a filter-compartment and a purified-water compartment, communicating with each other in the order named, valves for controlling the flow of water, inlet and outlet pipes, removable side plates on the filter-compartment, baffles-plates in the settling-compartment, and an overflow-opening formed in and extending practically the length of the settling-compartment and located above the normal level of the water therein, substantially as and for the purposes hereinbefore set forth.

700,827. SWIVEL-BLOCK. ALBERT E. BELMONT, Cambridge, Mass. Filed Aug. 2, 1901. Serial No. 70,791. (No model.)

Claim.—1. A swivel-block comprising a vertical spindle provided

with means for rigidly affixing it to an outtrigger-shaft, said spindle being provided near its lower end with a conical collar and screw-threaded at its upper end, a sleeve mounted on said spindle and carrying an out-pipe (equipped with an approximately horizontal arm provided at its free end with a vertical arm, and a pivoted latch connecting the upper end of the vertical arm to the sleeve, said sleeve being provided at its opposite ends with conical recesses or bearings, the lower of said bearings fitting the conical collar on the spindle, a cone adjustably fitted on the upper threaded end of the spindle and fitting the upper conical bearing in the spindle, a check-rod fitted on the spindle over the cone, and a post provided with means for fixing its lower end to the outtrigger-shaft, the spindle and connected at its upper end to the upper end of the spindle, substantially as described.

2. In combination with a shaft or beam, an outtrigger-shaft D, secured at one end to the shaft or beam by means and having a spindle K, secured to said shaft and a revolute pivotally arranged on said spindle, a post (L), secured to said shaft and to the upper end of the spindle K, and a brace or stay (H), secured at its end to the spindle K, and at its lower end to the opposite portion of the shaft or beam substantially as and for the purpose set forth.

700,828. SUSPENSION-BUCKLE. MAX ROSEN, New York, N. Y. Filed Mar. 1, 1901. Serial No. 92,828. (No model.)

Claim.—1. A suspension-buckle composed of a single piece of sheet metal, having three parallel bars united by end bars, the intermediate bar being in a plane behind that of the two adjacent bars and having open ends, the end bars having their inner edges bent inward and toward the intermediate bar to form clamping edges, the open ends of the intermediate bar being inclined upward and outward and in the direction toward the front face of the buckle, substantially as set forth.

2. A suspension-buckle constructed of a single piece of sheet metal and having the top and bottom bars A and B, the inner edges of which are inclined inward, the intermediate bar C is in a plane behind that of the bars A and B, and having open ends which are inclined upward and outward toward the face of the buckle, the end bars D having their outer edges bent over on the rear, substantially as set forth.

3. A suspension-buckle constructed of a single piece of sheet metal and having the top and bottom bars A and B, and the intermediate bar C in a plane behind that of the bars A and B, and having open ends which are inclined upward and outward toward the face of the buckle, the end bars D having their outer edges bent over on the rear, and the curved parts E uniting the end bars with the end parts of the bar C, substantially as set forth.

700,829. SELF-PLAYING ATTACHMENT FOR MUSICAL INSTRUMENTS. HENRY B. HARRIS, New York, N. Y., assignor to The Firm of Loewy and Company, New York, N. Y. Filed Apr. 27, 1901. Serial No. 92,794. (No model.)

Claim.—1. In a self-playing attachment for musical instruments, the combination with a note-sheet-rolling mechanism, of a reversing-gear for said sheet-rolling mechanism, pneumatic mechanism for operating the reversing-gear and means for pneumatically controlling the reversing-gear from a roller of the sheet-rolling mechanism, substantially as herein shown and described.

2. In a self-playing attachment for musical instruments, the combination with a note-sheet-rolling mechanism, of a reversing-gear for said sheet-rolling mechanism, pneumatic mechanism for operating the reversing-gear and means for pneumatically controlling the reversing-gear from a roller of the sheet-rolling mechanism, substantially as herein shown and described.

3. In a self-playing attachment for musical instruments, the combination with a note-sheet-rolling mechanism, of a driving-gear, a reversing-gear and means for controlling the reversing-gear pneumatically from a roller of the sheet-rolling mechanism, substantially as herein shown and described.

4. In a self-playing attachment for musical instruments, the combination with a note-sheet-rolling mechanism, of a driving-gear, a reversing-gear, pneumatic mechanism for operating the reversing-gear and means for pneumatically controlling said reversing-gear from a roller of the sheet-rolling mechanism by the unrolling of the sheet, substantially as herein shown and described.

5. In a self-playing attachment for musical instruments, the combination with two note-sheet rollers, one of said rollers having a dust extending from one end to the surface of the roller, a driving-gear, a reversing-gear, pneumatic mechanism for operating the reversing-gear, and a pneumatic connection between the said pneumatic mechanism and the said dust in the roller, substantially as herein shown and described.

6. In a self-playing attachment for musical instruments, the combination with two note-sheet rollers, one of said rollers having a dust extending from one end to the surface of the roller, a tubular bearing for that end of the roller having the dust, a driving-gear, a reversing-gear, pneumatic mechanism for operating the reversing-gear and a pneumatic connection between the said tubular bearing and the pneumatic mechanism for operating the reversing-gear, substantially as herein shown and described.

7. In a self-playing attachment for musical instruments, the combination with two note-sheet rollers, one of said rollers having a dust extending from one end to the surface of the roller, a spring-pressed tubular bearing for that end of the roller having the dust, a driving-gear, a reversing-gear, pneumatic mechanism for operating the reversing-gear and a pneumatic connection between the said tubular bearing and the pneumatic mechanism for operating the reversing-gear, substantially as herein shown and described.

8. In a self-playing attachment for musical instruments, the combination with two note-sheet rollers, one of said rollers having a dust extending from one end to the surface of the roller, a tubular spring-pressed bearing for one end of the said roller, a resilient bearing for the other end, a driving-gear, a reversing-gear, pneumatic mechanism for operating the reversing-gear and a pneumatic connection between the said tubular bearing and the pneumatic mechanism for operating the reversing-gear, substantially as herein shown and described.

9. In a self-playing attachment for musical instruments, the combination with a note-sheet-rolling mechanism, of a driving-gear for this rolling mechanism, a compressed-air-cumulating tube, a valve in said tube, a motor-tube, a valve in said motor-tube, a reversing-gear for the rolling

mechanism, means operated with said reversing-gear for controlling the valves in the compressed-air tube and suction-tube and pneumatic mechanisms connected with said compressed-air tube and suction-tube, substantially as herein shown and described.

10. In a self-playing attachment for musical instruments, the combination with a note-sheet-rolling mechanism, of a driving-gear for this rolling mechanism, a compressed-air tube, a valve in the same, a suction-tube, a valve in the same, a separate tube connected with the casing of each of said valves, a controlling-valve in the end of each of said tubes, a reversing-gear for the roller-driving mechanism, means connected with the reversing-gear for actuating the valve in the end of the said tube and pneumatic mechanism connected with the compressed-air tube and the suction-tube, substantially as herein shown and described.

11. In a self-playing attachment for musical instruments the combination with a series of pneumatic mechanisms, means for moving said valves by motion, a compressed-air-conducting tube, connected with the pneumatic mechanisms, a suction-tube connected with the valve mechanisms of said pneumatic mechanisms, a valve in the suction-tube, a valve in the compressed-air-conducting tube, a note-sheet-moving mechanism, a driving-gear for the same, a reversing-gear and means connected with the reversing-gear for controlling the valves in the suction-tube and in the compressed-air-conducting tube, while reversing, substantially as herein shown and described.

12. In a self-playing attachment for musical instruments the combination with a tracker-bar having ducts and a chamber connected with each duct, of a tube extending to said chamber, a suction-tube and a compressed-air tube and a three-way cock connecting the tube extending to said chamber with the suction-tube and the compressed-air tube, substantially as herein shown and described.

13. In a self-playing attachment for musical instruments, the combination with a tracker-bar having ducts and a chamber connected with each duct, of means for drawing air from said chamber and means for conducting compressed air into said chamber, substantially as herein shown and described.

14. In a self-playing attachment for musical instruments, the combination with a tracker-bar having ducts, of tubes connected with the ducts, a three-way cock connected with each of a series of such tubes and means in each tube, between the ends of tracker-bar ducts and the three-way cock for closing each duct or tube connected therewith, substantially as herein shown and described.

15. In a self-playing attachment for musical instruments, the combination with a tracker-bar having ducts, and additional ducts extending from the first-mentioned ducts, means for opening and closing said additional ducts automatically by a note-sheet moved over the tracker-bar, substantially as herein shown and described.

16. In a self-playing attachment for musical instruments, the combination with a tracker-bar having ducts and additional ducts extending from the first-mentioned ducts, of means for opening and closing said additional ducts automatically by a note-sheet moved over the tracker-bar, substantially as herein shown and described.

17. In a self-playing attachment for musical instruments, the combination with a pedal-operating bar, of a pneumatic mechanism for operating said bar, a tracker-bar, a tube extending from the said pneumatic mechanism to the tracker-bar and a three-way cock in said tube, substantially as herein shown and described.

18. In a self-playing attachment for musical instruments, the combination with a series of pneumatic mechanisms to be operated by compressed air, of valve mechanisms for said pneumatic mechanisms, means for operating said valves by motion, a compressed-air-conducting tube, a valve-casing connected with said tube, a valve in said casing controlling said compressed-air-conducting tube, a suction-tube, a valve-casing connected therewith, a valve in the same controlling the suction-tube, a note-sheet-rolling mechanism, a reversing-gear for the same, a tube connected with the valve-casing of the compressed-air tube, a tube connected with the valve-casing of the suction-tube and means for opening or closing said two tubes together automatically, which means are operated with the reversing-gear, substantially as herein shown and described.

700,880. PLAYING ATTACHMENT FOR MUSICAL INSTRUMENTS. HARRY H. SALTER, New York, N. Y., assignor to The Firm Ludwig and Company, New York, N. Y. Filed June 17, 1921. Serial No. 94,895. (No model.)

Claim.—1. In a playing attachment for musical instruments, a pneumatic mechanism composed of a casing, a rod in the same, means in the casing for moving the rod lengthwise by compressed air, a valve for admitting compressed air into said casing, a spring acting on said valve to prevent the same and means for counteracting said spring by motion, and means for automatically destroying said motion, in time, substantially as herein shown and described.

2. In a playing attachment for musical instruments, a pneumatic mechanism composed of a casing, means in the same for moving a rod lengthwise by compressed air, a rod in said casing, a valve for admitting compressed air into said casing, a spring acting on said valve to prevent the same and means for counteracting said spring by motion, substantially as herein shown and described.

3. In a playing attachment for musical instruments, a pneumatic mechanism composed of a casing, means in the same for moving a rod lengthwise by compressed air, a rod in said casing, a valve for admitting compressed air into said casing, a spring acting on said valve to prevent it and a diaphragm and suction-tube for counteracting said spring, substantially as herein shown and described.

4. In a playing attachment for musical instruments a pneumatic mechanism composed of a casing, means in the same for moving a rod lengthwise by compressed air, a rod in said casing, a valve for admitting compressed air into said casing, a motion device for actuating the valve, and a spring for moving the valve, substantially as herein shown and described.

5. In a playing attachment for musical instruments a pneumatic mechanism composed of a chamber, a suction-duct connected with said chamber, a diaphragm in the chamber, a valve-stem impinging on said diaphragm and a spring for moving the diaphragm adversely to the spring, substantially as herein shown and described.

6. In a playing attachment for musical instruments a pneumatic mechanism composed of a chamber, a suction-duct connected with said chamber, a diaphragm in the chamber, means for admitting atmospheric air to one face of the diaphragm, a spring for pressing said diaphragm adversely to the pressure of the atmospheric air and a valve-stem impinging against the diaphragm, substantially as herein shown and described.

7. In an automatic playing attachment for musical instruments, the combination with a series of pneumatic mechanisms to be operated by compressed air, of valves for the same, means for controlling said mechanisms by motion, a compressed-air-supply tube, a valve-casing in said tube, a valve in said casing and means for controlling said valve by motion, a suction-tube, a valve-casing in the suction-tube, a valve in the same, and a tube extending from the valve-casing in the compressed-air tube to the suction-tube, substantially as herein shown and described.

8. In an automatic playing attachment for musical instruments the combination with a series of pneumatic mechanisms to be operated by compressed air, of valves for the same, means for controlling said mechanisms by motion, a compressed-air-supply tube, a valve-casing in said tube, a valve in said casing and means for controlling said valve by motion, a suction-tube, a valve-casing in the suction-tube, a valve in the same, and a tube extending from the valve-casing in the compressed-air tube to the suction-tube, substantially as herein shown and described.

700,881. FULLER. PNEUMATIC RECORDING. Chicago, Ill. Filed Apr. 20, 1921. Serial No. 57,897. (No model.)

Claim.—1. In a furnace, the combination with a traveling chain grate, of a wind-box at the rear of the furnace provided with upper and lower openings between which the grate is disposed, so that air is blasted through the grate in both directions, substantially as described.

2. In a furnace, the combination with a traveling chain grate, of a wind-box at the rear thereof projecting above the grate and having its upper end constituting a lodging-place for the accumulated fuel, the air passing through the wind-box serving to cool the metal thereof, whereby the wind-box may withstand the temperature of the burning fuel, a passage being provided between the wind-box and the bridge-wall of the furnace, through which ashes from the fuel may pass, an ash-pit being provided beneath the furnace for receiving the ashes, and a door for closing the said passage-way to the ash-pit when the ashes are to be removed, substantially as described.

3. In a furnace, the combination with a traveling chain grate, of a wind-box at the rear thereof projecting above the grate and having its upper end constituting a lodging-place for accumulated fuel, the air passing through the wind-box serving to cool the metal thereof, whereby the wind-box may withstand the temperature of the burning fuel, the upper part of the wind-box being formed with a pivotal section, substantially as described.

4. In a furnace, the combination with a traveling chain grate, of a wind-box at the rear thereof projecting above the grate and having its upper end constituting a lodging-place for accumulated fuel, the air passing through the wind-box serving to cool the metal thereof, whereby the wind-box may withstand the temperature of the burning fuel, substantially as described.

5. In a furnace, the combination with a traveling chain grate, of a traveling carriage for supporting the same, a deflecting-plate located between the stretches of the chain grate and mounted upon the side walls of the said frame, and means at the rear of the furnace for directing a blast of air upon the said deflecting-plate, which thereupon serves to redirect the blast of air upwardly through the fuel, substantially as described.

6. In a furnace, the combination with a traveling chain grate, of means at the rear thereof for directing a blast of air upon the fuel, the front of the furnace being provided with cooling means and a duct beneath the traveling chain grate forming, with the front of the furnace, means for cooling the same, and constituting a support for receiving the fuel falling through the grate before it is consumed, an ash-pit provided beneath the duct, and a passage-way at the rear of the grate through which ashes from the grate may fall into the ash-pit, substantially as described.

7. In a furnace, the combination with a traveling chain grate, of means at the front of the furnace for placing fuel upon the grate, a wind-box at the rear of the furnace provided with means at its upper end constituting an abutment or lodging-place against which fuel may be accumulated to more readily permit its consumption, and a deflecting-plate for directing the blast of air upwardly through this accumulated fuel, substantially as described.

8. In a furnace, the combination with a traveling chain grate, of means at the front of the furnace for placing fuel upon the grate, and a wind-box at the rear of the furnace provided with means at its upper end constituting an abutment or lodging-place against which fuel may be accumulated to more readily permit its consumption, substantially as described.

9. In a furnace, the combination with a traveling chain grate, of means at the front of the furnace for feeding fuel upon the grate, means for creating a forced blast at the rear of the furnace upon the fuel, and a deflecting-plate co-operating with the blast-creating means and serving to direct the blast of air upwardly through the fuel, substantially as described.

10. In a furnace, the combination with fuel-supporting means, of means at the front of the furnace for placing fuel upon the fuel-supporting means, a wind-box at the rear of the furnace constituting an abutment against which the fuel may be gathered, and a deflecting-plate located below the fuel, the said wind-box serving to direct a blast of air upon the deflecting-plate, the latter serving to deflect the blast of air up through the fuel, substantially as described.

11. In a furnace, the combination with a traveling chain grate, of a traveling carriage for supporting the same, an adjustable deflecting-plate located between the stretches of the chain grate and mounted upon the side walls of the said frame, and means at the rear of the furnace for directing a blast of air upon the said deflecting-plate, which thereupon serves to redirect the blast of air upwardly through the fuel, substantially as described.

12. In a furnace, the combination with a traveling chain grate, of means at the front of the furnace for placing fuel upon the grate, a wind-box at the rear of the furnace provided with means at its upper end constituting an abutment or lodging-place against which fuel may be accumulated to more readily permit its consumption, and an adjustable deflecting-plate for directing the blast of air upwardly through this accumulated fuel, substantially as described.

13. In a furnace, the combination with a traveling chain grate, of means at the front of the furnace for feeding fuel upon the grate, means for creating a forced blast at the rear of the furnace upon the fuel, and an adjustable deflecting-plate co-operating with the blast-creating means and serving to direct the blast of air upwardly through the fuel, substantially as described.

14. In a furnace, the combination with a traveling chain grate, of means at the front of the furnace for feeding fuel upon the grate, means for creating a forced blast at the rear of the furnace upon the fuel, and an adjustable deflecting-plate co-operating with the blast-creating means and serving to direct the blast of air upwardly through the fuel, substantially as described.

700,882. APPARATUS FOR DYING. Dr. PAUL SCHMIDT, Berlin, Germany. Filed Feb. 4, 1922. Serial No. 82,226. (No model.)

Claim.—1. In an apparatus for drying, bleaching, washing and otherwise treating textile materials by liquids in combination with a fluid rot containing the liquid, a tub 1 containing the material to be treated with the liquid, said tub being supported on a lifting apparatus capable of lowering the same into basin or raising it out of it, while the lifting-gear itself is carried on a frame 2, 3, 4 on which 5 for the purpose of withdrawing the raised tub together with the lifting-gear away from the basin 1, as described and illustrated.

2. In a combination with the tub 1 a frame 2, 3, 4, pressure-cylinders 6 fixed on girders 4 of said frame, pistons 7 in said cylinders, forced bearings 8 formed at the top of pistons 7 to carry the tub 1 on pins 9 projecting from the two opposite sides of the tub, a bracket 11 extending from the side of one of the pistons 7, a spindle 12 carried in said bracket, a spur-wheel 10 keyed to the end of pin 9 and gearing into a pinion 11 on spindle 12, a crank 13 at the end of spindle 12, a pipe 14 leading into the pressure-cylinder 6, the whole as described and illustrated and for the purpose set forth.

3. In an apparatus for drying, bleaching, washing and otherwise

treating textile materials by liquids in combination with a basin 5, a pump 17, a flexible tube 17 and a movable tab 1, said tube 17 being connected at one end to the basin of a gulchman 16 leading into the interior of said tub the whole as described and illustrated and for the purpose set forth.

4. In an apparatus for dyeing, bleaching, washing and otherwise treating textile material with liquids, in combination with a tub 1 perforated diaphragm 20, 20 in the middle of the same and forming a chamber 21 between them for introducing the liquid therein and two spaces 22 at both sides of this chamber, false perforated covers 23 for each of these spaces, closing-covers 18, 19, pump-glasses 25 fitted in said covers 18, 19 respectively, levels 20 along the edges of said covers fitting to corresponding levels 21 along the respective edges of the tub 1, fastening-covers 22 for pulling the covers 18, 19 tight against the edges of the tub, the whole as described and illustrated and for the purpose set forth.

5. In combination with the tub 1 having outlets 24 between the bottom 23 and the covers 18 and 19, the throttle-valves 25 actuated by levers 26, bolts 27 and quadrants 28, for regulating the width of the outlet of the liquid from the tub back into the vat, the whole as described and illustrated.

700,888. MANUFACTURE OF FERMENTED LIQUORS. JOHN SHERMAN, New York, N. Y. Filed Feb. 22, 1902. Serial No. 94,898. (No model.)

Claim.—1. The improvement in the art of manufacturing fermented liquor which consists in carrying on the first or main fermentation in a closed vessel, separating the liquor with the active yeast from the waste yeast and foreign matter, transferring the liquor carrying in suspension the yeast for further use to another vessel, separating, in the second vessel, the liquor from such yeast, and removing the liquor and introducing other liquor to be fermented into the second vessel without removing the yeast therefrom.

2. The improvement in the art of manufacturing fermented liquor which consists in carrying on the first or main fermentation in a closed vessel, separating the liquor with the active yeast from the waste yeast and foreign matter transferring the liquor carrying in suspension the yeast for further use to another closed vessel, separating, in the second vessel, the liquor from such yeast, and removing the liquor and introducing other liquor to be fermented into the second vessel without removing the yeast therefrom, and carrying the liquor introduced with the yeast as soon as a rise in the temperature manifests itself.

700,884. PACKING FOR PRESSURE-PYTONS. ALBERT BIRALL, Manchester, Germany. Filed Sept. 16, 1901. Serial No. 75,593. (No model.)

Claim.—1. The combination with a pressure-cylinder and a plurality of cylinders α connected concentrically to said pressure-cylinder, of a piston adapted to be reciprocated in said pressure-cylinder, a plurality of other cylinders β connected concentrically to said piston and adapted

to be reciprocated therewith in the annular space respectively formed by the cylindrical cylinders α and cooling liquid as disposed in said annular space as to severally seal each from the next and to provide a combined columnar pressure exceeding that equivalent to the length of the stroke of the piston.

2. The combination with a pressure-cylinder and a plurality of cylinders α connected concentrically to said pressure-cylinder, a piston adapted to be reciprocated in said pressure-cylinder, a plurality of other cylinders β connected concentrically to said piston and adapted to be reciprocated therewith in the annular space respectively formed by the cylindrical cylinders α and cooling liquid as disposed in said annular space as to severally seal each from the next and to provide a combined columnar pressure exceeding that equivalent to the length of the stroke of the piston.

700,885. FUSE-PIVOT FOR MORTAR-FUSE. JAMES T. GUNN, London, England, Denmark. Filed Sept. 16, 1901. Serial No. 75,594. (No model.)

Claim.—In combination with the stand, a pivot-rod 1 supported thereon, a pivot-foot 4 pivoted within the stand, a worm 3 for operating the pivot-foot, a platform carried by the pivot-foot, a pivot-rod 6 supported on the platform, an arm 7 pivoted in the pivot-rod, an arm 10 inserted within the arm 7, said arm being arranged to support the weapon and having between them and the pivot-rod 6 control friction-surfaces 17, 18, 19 and 20, means for adjusting the frictional contact between said surfaces including a resilient device and an adjusting device, the said arm 7 having an upwardly-extending branch in the form of a fork provided with hook-shaped bearings 24, a movable locking-disk 9 carried by the upwardly-extending portion of the arm 7 and cooperating with the hook-shaped bearings, the said arm 10 being provided with the steering-disk 11, a rotary body 12 journaled therein, an elevation-rod 13 supported by said rotary body, and means for adjusting the elevation-rod, substantially as described.

700,886. ILLUMINATED SIGN. CHARLES G. SWIFT, Boston, Mass., assignor to Alfred G. Feltus and Marie L. Feltus, copartners doing business as A. G. and M. L. Feltus, a firm of Boston, Mass. Filed Feb. 11, 1902. Serial No. 95,899. (No model.)

Claim.—1. In an illuminated sign, light-receiving surface, a shaded background therefor comprising a series of shadow-forming projections, and a light in front and to one side of said background, said projections being transversely disposed with relation to the rays of the light and adapted to intercept the rays to said background, substantially as described.

2. In an illuminated sign, light-receiving surface, a shaded background therefor comprising a series of parallel shadow-forming projections, and a light in front and to one side of said background, said projections being transversely disposed with relation to the rays of the light and adapted to intercept the rays to said background, substantially as described.

3. In an illuminated sign, light-receiving surface, a shaded background therefor comprising a series of shadow-forming projections, and a light, said light-receiving surface being slightly inclined with relation to said background and toward the light, substantially as described.

4. In an illuminated sign, light-receiving surface, a shaded background therefor consisting of a board provided with a series of angular shadow-forming ridges, and a light in front and to one side of said board, said ridges being transversely disposed with relation to the rays of the light and adapted to intercept the rays to said background, substantially as described.

5. In an illuminated sign, light-receiving surface, a shaded background therefor consisting of a board provided with a series of angular shadow-forming ridges, and a light, said light-receiving surface being slightly inclined with relation to said board and toward the light, substantially as described.

6. In an illuminated sign, light-receiving character upon a shaded background said background consisting of a board having a corrugated surface, and a light in front and to one side of said board, the corrugations of said surface facing toward the light at an angle such that the narrow faces of the corrugations receive the light and are out of the range of vision from a point of observation in front of the sign, while the broad faces of the corrugations are shaded from the light and are within the range of vision from said point of observation, the faces of the said light-receiving character being slightly inclined with relation to the said board and toward the light, substantially as described.

7. In an illuminated sign, light-receiving character upon a shaded background, said background consisting of a board having a corrugated surface, and a light in front and to one side of said board, the corrugations of said surface facing toward the light at an angle such that the narrow faces of the corrugations receive the light and are out of the range of vision from a point of observation in front of the sign, while the broad faces of the corrugations are shaded from the light and are within the range of vision from said point of observation, the faces of the said light-receiving character being slightly inclined with relation to the said board and toward the light, substantially as described.

8. In an illuminated sign, light-receiving surface, a shaded background therefor comprising a series of transverse shadow-forming projections, and a light in front and to one side of said sign, the shadow-forming projections which are more remote from the light being spaced at greater intervals than the projections nearer the light, substantially as described.

700,887. SOLID-RUBBER VEHICLE-TIRE. FRANK A. SHERRILL, Akron, Ohio. Filed Jan. 15, 1902. Serial No. 95,900. (No model.)

Claim.—1. An improved solid-rubber vehicle-tire having a rounded tread portion, with lateral flanges on each side of the base, and a downwardly-curved base, and having embedded transverse wires or rods curved downward, in the center from near the center of the rubber tire on each side to the base, thence diagonally upward to the upper inner angle of the flanges and the, substantially as shown and described.

2. An improved solid-rubber vehicle-tire having a tread portion, a base, and lateral flanges on each side of the base, having at intervals embedded transverse wires or rods curved downward in the center from near the center of the rubber on each side to the base, thence diagonally upward to the upper parts of the flanges, substantially as shown and for the purpose specified.

3. The combination with a metallic tire having lateral, inward flanges forming channels, of a rubber tire adapted to rest in said metal tire having lateral flanges to fit said channels, and having at intervals, embedded wires or rods in planes transverse to said rubber tire centrally curved downward from near the center of the rubber on each side to the base, and thence diagonally upward into the flanges near their upper faces, substantially as shown and described.

700,888. ATOMIZER. OTTO J. SCHMIDT, Philadelphia, Pa., assignor to Rhodes Lockwood, William H. Lockwood, and Rhodes C. Lockwood, copartners under firm-name of Devision Rubber Company Boston, Mass. Filed May 2, 1901. Serial No. 94,817. (No model.)

Claim.—1. An atomizer made up of a bulb; a receptacle fitting into the mouth of the bulb and having a sliding engagement therewith and a passage through its walls communicating at the lower end of the receptacle with the interior of the bulb and opening at its upper end into the upper interior portion of the receptacle to permit the passage of air under pressure from the bulb to the upper interior end of the receptacle when the bulb is compressed; and a spraying device at the free end of the receptacle, having a pipe depending within the receptacle.

2. An atomizer made up of a bulb; a double-walled receptacle, having a space between the walls and an aperture through the outer wall at the lower end thereof and an aperture through the inner wall at the upper end thereof; a spraying device at the mouth of the receptacle, having its liquid-pipe depending within the inner wall of the receptacle; all organized and arranged, substantially as shown and described, to permit the passage of air under pressure from the bulb to the upper interior end of the receptacle, when the bulb is compressed.

700,889. MAGNETIC CLUTCH. FRANK L. SHERRILL, Calumet, Ill., assignor to Sherrill & Sherrill, Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Sept. 5, 1901. Serial No. 75,595. (No model.)

Claim.—The combination with two rotatable parts mounted to rotate in opposite directions, of an intermediate freely-rotatable part, causing series of pole-pieces on each of the first two parts arranged in juxtaposition to similar series of pole-pieces on the intermediate part, a fourth annular part extending around the rotatable parts, and coils of wire inclosed between the fourth part and rotatable parts and extending circumferentially in proximity to each of the two sets of pole-pieces, whereby the freely-rotatable part will be rotated in the one direction or the other according as one or the other of the coils is energized.

700,840. PNEUMATIC TIRE. RICHARD SMITH, Vernon Beach, near Bangor, England, assignor to John Smith, Troy, N. Y., and Harry Smith, New York, N. Y. Filed Apr. 22, 1902. Serial No. 100,500. (No model.)

Claim.—1. In a vehicle-tire, the combination with an annular disc including having an outermost convex tread, and an innermost concave

lined annular seat; of a flattened metallic armor-band extending around the interior of the tire in engagement with the flattened seat on the shoe and wholly inclosed within the shoe; an inner removable air-tube of circular cross-section; and a separate cradle-band interposed between said inner tube and armor-band and having a flattened outer surface engageable with said armor-band and a concaved inner surface adapted to receive and support said circular inner tube, said armor-band and cradle-band being adapted to be maintained in position between said shoe and inner tube by inflation of said inner tube, substantially as described.

2. In a vehicle-tire, the combination with an annular outer tube having an unbroken increased tread, and an interiorly-located flattened annular seat; of a flattened metallic armor-band extending around the interior of the tire in engagement with the flattened seat on said outer tube; an inner air-tube of circular cross-section inclosed within the outer tube; and a separate cradle-band interposed between said inner tube and armor-band and having a flattened outer surface engageable with said armor-band and a concaved inner surface adapted to receive and support said circular inner tube; and a fabric lining for said outer tube covering said seat and inclosing said armor-band, cradle-band and inner tube, substantially as described.

700,841. BICYCLE-PUMP. RUSSELL F. SMITH, Stockton, Cal. Filed Sept. 9, 1901. Serial No. 74,781. (No model.)

Claim.—1. In a bicycle-pump of the class described, the combination: a frame-tube formed to compose the pump barrel or body and having its lower end closed, a nipple to receive the hose, a middle-post having its top end closed with two small openings arranged therein, and adjustably secured in the top end of the pump-barrel, a plunger-rod inserted into one of said openings and having a suitable plunger attached thereto, a suitable clamp rigidly attached to the hose and adapted to engage the plunger-rod and protrude into the opening 9 and the arm 13 attached to said middle-post, all arranged and operating substantially as shown and described and for the purposes set forth herein.

2. In a bicycle-pump, the combination with a suitable pump-barrel formed in the frame and provided with a suitable plunger and plunger-rod of the middle-post 6 inserted in the top of the pump-barrel and having the top end closed but the openings 9 and 9', the hose secured to said plunger-rod by the spring-clamp 19 and introduced into the opening 9, the cap 10 seated over the end of the said middle-post 6 and having the side 11 flattened, the springs 12 secured to the side 11, the shield 13 rigidly attached to the plunger-rod and adapted to engage with the springs 12, all arranged and operating substantially as shown and described and for the purposes specified.

700,842. PNEUMATIC WALKING-DRUM. RUSSELL F. SMITH, Stockton, Cal. Filed Dec. 24, 1902. Serial No. 83,828. (No model.)

Claim.—1. A rotary pneumatic walking-drum having a series of air-distributing flues arranged therein at intervals of a circle, a correspond-

ing series of independent counterbalanced gates in pivotal connection with an air-chamber wall of the drum to severally control the inlet ends of the respective flues, and steps on said partition arranged to limit automatic play of each gate.

2. A rotary pneumatic walking-drum having a central exhaust-air flue, a water-reservoir carried by the drum, and means for automatic distribution of the water from the reservoir to the interior of the drum at recurrent intervals.

3. A rotary pneumatic walking-drum, having a central exhaust-air flue, a water-reservoir carried by the drum and divided by radial partitions into compartments, a perforated pipe leading from each reservoir-compartment along said flue, valve mechanism controlling the pipes, and means whereby said mechanism is automatically actuated to open and close said pipes at recurrent intervals.

4. A rotary pneumatic walking-drum having a central exhaust-air flue, a water-reservoir carried by the drum and divided by radial partitions into compartments, a perforated valve-controlled pipe leading from each reservoir-compartment along said flue, each valve-stem being exposed and provided with a crank, a spring arranged with relation to each crank to resist swing of same in the direction necessary to meet the corresponding valve, and a stationary wiper in the path of the valve-stem cranks to actuate the same against spring resistance.

5. A rotary pneumatic walking-drum having a central exhaust-air flue, a water-reservoir carried by the drum and divided by radial partitions into compartments, a perforated valve-controlled pipe leading from each reservoir-compartment along said flue, each valve-stem being exposed and provided with a crank, a spring arranged with relation to each crank to resist swing of same in the direction necessary to meet the corresponding valve, a stationary bracket, and a plate in adjustable connection with the bracket to constitute a wiper in the path of the valve-stem cranks.

6. A rotary pneumatic walking-drum, having a central exhaust-air flue, an annular water-reservoir on a drum-head surrounding the inlet air-nozzle that projects from said head, and means for automatic distribution of the water from the reservoir to the interior of the drum at recurrent intervals.

7. A rotary pneumatic walking-drum having a forward air-chamber a central air-exhaust flue and air-distributing flues concentric with the exhaust-flue, counterbalanced pivoted gates each arranged to control the inlet end of an air-distributing flue, a water-reservoir carried by the drum and divided by radial partitions into compartments, a perforated valve-controlled pipe leading from each drum-compartment along the air-exhaust flue, and means for automatically opening and closing the pipe-valves.

700,848. MACHINE FOR SHAPING BOXES. WINFIELD S. SMITH, Fairview, N. J., assignor of one-half to Philip Stanley Smith, Philadelphia, Pa. Filed Nov. 27, 1901. Serial No. 88,898. (No model.)

Claim.—1. In a machine for shaping boxes, the combination with a support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, substantially as described.

2. In a machine for shaping boxes, the combination with a support for the box, of means for pressing the sides and ends of the box inward beyond the position they are designed to normally assume in the finished box, substantially as described.

3. In a machine for shaping boxes, the combination with a support for the box, of means for simultaneously pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, substantially as described.

4. In a machine for shaping boxes, the combination with a support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, and means being constructed to apply the pressure first at a point central of said sides and gradually approaching the ends thereof, substantially as described.

and means being constructed to apply the pressure first at a point central of said sides and gradually approaching the ends thereof, substantially as described.

5. In a machine for shaping boxes, the combination with a support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, said means being constructed to apply the pressure first at a point central of said sides and gradually and progressively applied to each side of the center to the ends of said sides, substantially as described.

6. In a machine for shaping boxes, the combination with a support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, said means being constructed to apply the pressure to the upper edges of said sides, substantially as described.

7. In a machine for shaping boxes, the combination with a support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, said means being constructed to apply the pressure to the upper edges of said sides, substantially as described.

8. In a machine for shaping boxes, the combination with a movable support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, said means being constructed to drop the box from between the pressure-blocks when the latter are retracted, substantially as described.

9. In a machine for shaping boxes, the combination with a movable support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, said means being constructed to drop the box from between the pressure-blocks when the latter are retracted, substantially as described.

10. In a machine for shaping boxes, the combination with a sliding and-filling support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, said means being constructed to drop the box from between the pressure-blocks when the latter are retracted, substantially as described.

11. In a machine for shaping boxes, the combination with a support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, said means being constructed to drop the box from between the pressure-blocks when the latter are retracted, substantially as described.

12. In a machine for shaping boxes, the combination with a support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, said means being constructed to drop the box from between the pressure-blocks when the latter are retracted, substantially as described.

13. In a machine for shaping boxes, the combination with a support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, said means being constructed to drop the box from between the pressure-blocks when the latter are retracted, substantially as described.

14. In a machine for shaping boxes, the combination with a support for the box, of means for pressing opposite sides of the box inward beyond the position they are designed to normally assume in the finished box, said means being constructed to drop the box from between the pressure-blocks when the latter are retracted, substantially as described.

15. In a machine for shaping boxes, the combination with a support for the box, of a stationary pressure-block detachably fixed on one side of the box-support, a movable pressure-block detachably arranged on the opposite side of the box-support, means for moving the movable pressure-block toward the box-support, and means for automatically retracting the movable pressure-block, substantially as described.

16. In a machine for shaping boxes, the combination with a support for the box, of a stationary pressure-block arranged on one side of the box-support, movable pressure-blocks arranged on the remaining sides of the box-support, means for moving the movable pressure-blocks toward the box-support, and means for automatically retracting the movable pressure-blocks, substantially as described.

17. In a machine for shaping boxes, the combination with an open-topped table, of a box-support arranged in said aperture, pressure-blocks slidably arranged on the table so as to be moved toward and from the box-support, means for moving the pressure-blocks toward the box-support to press the box, means for automatically retracting the pressure-blocks, and mechanism actuated during the retractile movement of the pressure-blocks for releasing the box-support to permit it to drop and discharge the box, substantially as described.

18. In a machine for shaping boxes, the combination with an open-topped table, of a box-support hinged at one side in said aperture, pressure-blocks slidably arranged on the table so as to be moved toward and from the box-support, means for moving the pressure-blocks toward the box-support, means for automatically retracting the pressure-blocks, and mechanism actuated by the retractile movement of the pressure-blocks for releasing the box-support whereby the latter may swing downward and discharge the box, substantially as described.

19. In a machine for shaping boxes, the combination with an open-topped table, of a box-support hinged at one side in said aperture, pressure-blocks slidably arranged on the table so as to be moved toward and from the box-support, means for moving the pressure-blocks toward the box-support, means for automatically retracting the pressure-blocks, means actuated by the retractile movement of the pressure-blocks for releasing the box-support to permit it to swing downward to discharge the box, and means for automatically restoring the box-support to normal position, substantially as described.

20. In a machine for shaping boxes, the combination with an open-topped table, of a box-support hinged at one side in said aperture and provided on its under side with a pendant cam, pressure-blocks slidably arranged on the table so as to be moved toward and from the box-support, means for moving the pressure-blocks toward the box-support, means for retracting the pressure-blocks, a pusher-bar arranged to engage the pendant cam to raise the box-support, a spring for moving the pusher-bar in the proper direction to raise the box-support, and mechanism actuated by the retractile movement of the pressure-blocks for withdrawing the pusher-bar to permit the box-support to swing downward, substantially as described.

21. In a machine for shaping boxes, the combination with an open-topped table, of a box-support hinged at one side in said aperture and provided on its under side with a pendant cam, pressure-blocks slidably arranged on the table so as to be moved toward and from the box-support, means for moving the pressure-blocks toward the box-support, means for retracting the pressure-blocks, a pusher-bar arranged to engage the pendant cam, a hook on the opposite end of the pusher-bar, an oscillatory latch movable with one of the pressure-blocks and arranged to engage and withdraw the pusher-bar to drop the box-support when the pressure-blocks are retracted, a spring for moving the pusher-bar in a direction to raise the box-support, and a cam arranged in the path of the latch and operating to oscillate the latch and release the pusher-bar, substantially as described.

22. In a machine for shaping boxes, the combination with an open-topped table, of a box-support hinged at one side in said aperture and provided on its under side with a pendant cam, pressure-blocks slidably arranged on the table so as to be moved toward and from the box-support, means for retracting the pressure-blocks, a pusher-bar arranged to reciprocate in a suitable support and adapted to engage at one end the pendant cam, a hook on the opposite end of the pusher-bar, an oscillatory latch movable with one of the pressure-blocks and provided at one end with a hook adapted to engage the hook on the pusher-bar and withdraw the latter to drop the box-support, a spring for drawing said latch into engagement with the pusher-bar, an adjustable cam arranged in the path of the latch and operating to cause the latter to release the pusher-bar, and a spring for moving the pusher-bar in a direction to raise the box-support, substantially as described.

23. In a machine for shaping boxes, the combination with a table provided with a box-support, of sliding carriages movably arranged in ways on the table so as to be moved toward and from the box-support, and carrying pressure-blocks, a treadle, flexible connections between the treadle and said carriages and operating when the treadle is depressed to

move the carriages and pressure-blocks toward the box-support, and springs for retreating the carriages and pressure-blocks, substantially as described.

34. In a machine for shaping boxes, the combination with a table provided with a box-support, of sliding carriages movably arranged in ways in the table so as to be moved toward and from the box-support, pressure-blocks removably carried by said carriages, a treadle, flexible connections leading from the treadle to the carriages, guide-pulleys over which the flexible connections pass, said treadle operating when depressed to move the carriages and pressure-blocks toward the box-support, and springs for retreating the carriages and pressure-blocks, substantially as described.

35. In a machine for shaping boxes, the combination with a table provided with a box-support and having grooved ways extending at right angles to the box-support, blocks movably arranged in said ways and carrying cross-bars, each of said cross-bars being provided on its inner face with a longitudinal dovetailed groove, pressure-blocks each having attached to its outer edge a dovetailed strip, said strips being removably fitted in said grooves, a treadle and intermediate connections for moving the pressure-blocks toward the box-support, and springs arranged to move the pressure-blocks away from the box-support, substantially as described.

36. In a machine for shaping boxes, the combination with a support for the box, of carriages arranged to move toward and from the support, a pressure device carried by each carriage, each pressure device comprising separate blocks adjustable toward and from each other, and means for moving said pressure devices toward the box-support with a positive pressure.

37. In a machine for shaping boxes, the combination with a support for the box, of pressure devices arranged to move toward and from the support, each pressure device comprising separate blocks adjustable toward and from each other, and means for moving said pressure devices toward the box-support with a positive pressure.

38. In a machine of the class described, a pressure-block formed of independently-adjustable sections, each section having a pressing-face constructed to press the side of a box inward beyond the position said side is designed to assume in the finished box.

39. In a machine of the class described, a pressure-block formed of independently-adjustable sections, each section having a pressing-face constructed to press the side of a box inward beyond the position said side is designed to assume in the finished box, and means for adjusting said sections toward and from each other.

40. In a machine of the class described, a pressure-block comprising a fixed central section, and adjustable end sections.

41. In a machine of the class described, a pressure-block comprising a fixed central section and adjustable end sections, and means for moving the end sections toward and from the central section.

42. In a machine of the class described, a pressure-block having an outwardly-curved pressing-face adapted to press the side of a box inward beyond the position it is designed to assume in the finished box.

43. In a machine of the class described, a pressure-block having a convex pressing-face adapted to press the side of a box inward beyond the position it is designed to assume in the finished box.

44. In a machine of the class described, a pressure-block having a curved or convex edge the outer side of which is undercut or recessed.

45. In a machine for shaping boxes, means arranged to rest upon the sides of the box and bend said sides inward beyond the position they are designed to assume in the finished box.

46. In a machine for shaping paper boxes, means arranged to rest upon the sides of the box and bend said sides inward beyond the position they are designed to assume in the finished box, and means for actuating said bending means.

47. In a machine for shaping boxes, means for simultaneously bending opposite sides of the box inward beyond the position they are designed to assume in the finished box.

48. In a machine for shaping boxes, the combination with a support for the box, of means for bending opposite sides of the box inward beyond the position they are designed to assume in the finished box, and means for actuating said bending means.

700,844. MAIL-POUCH. GARRETT F. SUMNER, Alhambra, Iowa.
Filed May 17, 1891. Serial No. 68,894. (No model.)

Claim.—The combination with a flexible mail-pouch open at one end, of two rigid side pieces 12, and two rigid end pieces 13, said side pieces being of a length substantially twice that of the end pieces, and said pieces being hinged together to form when open a rectangular figure and being secured to the open top of the pouch, whereby when closed the side pieces will overlap each other for a considerable portion of their length, one of said side pieces having two slots therein, two staples secured to the other side piece to enter and project through said slots when the frame is closed, a pin having a rounded end to pass through one of

the staples and having its other end flattened and slotted to permit the other staple to project through it, a chain for connecting said pin with the frame and lock to pass through the latter staple when the staple has been projected through the slot in the pin for the purpose stated.

700,845. CYLINDER RELIEF-VALVE. ALEXANDER STEWART, London, England. Filed Sept. 21, 1901. Serial No. 78,022. (No model.)

Claim.—1. A relief-valve arrangement for locomotive and other engines, comprising a series of chambers, a passage leading from one end of each chamber to a space to be relieved, a common steam-chamber into which the other ends of the series of chambers open, a relief-passage and, located in said series of chambers, a series of valves which control communication between said chambers and the relief-passage, said chambers and relief and steam passages being formed in one casting, as set forth.

2. A relief-valve arrangement for locomotive and other engines, comprising a series of chambers, a passage leading from one end of each chamber to a space to be relieved, a common steam-chamber into which the other ends of the series of chambers open, a relief-passage and, located in said series of chambers, a series of valves which control communication between said chambers and the relief-passage, said chambers and relief and steam passages being formed in one casting, a series of openings in said casting, one opposite each chamber and each closed by a cover-plate, as set forth.

3. A relief-valve arrangement for locomotive and other engines, comprising a series of chambers, a passage leading from one end of each chamber to a space to be relieved, a common steam-chamber into which the other ends of the series of chambers open, a relief-passage and, located in said series of chambers, a series of valves which control communication between said chambers and the relief-passage, said chambers and relief and steam passages being formed in one casting, and arranged in an annular row, as set forth.

4. A relief-valve arrangement for locomotive and other engines, comprising a series of chambers, a passage leading from one end of each chamber to a space to be relieved, a common steam-chamber into which the other ends of the series of chambers open, a relief-passage and, located in said series of chambers, a series of valves which control communication between said chambers and the relief-passage, said chambers and relief and steam passages being formed in one casting, and arranged in an annular row, and centrally-disposed means for actuating the casting to its support, as set forth.

5. A relief-valve arrangement for locomotive and other engines, comprising a series of chambers, a passage leading from one end of each chamber to a space to be relieved, a common steam-chamber into which the other ends of the series of chambers open, a relief-passage and, located in said series of chambers, a series of valves which control communication between said chambers and the relief-passage, a steam-supply, pipe connections between said steam-supply and steam-chamber, and a three-way cock, one branch being connected to the steam-supply, one to the steam-chamber and the third to waste, as set forth.

6. A relief-valve arrangement for locomotive and other engines, com-

prising a series of chambers, a passage leading from one end of each chamber to a space to be relieved, a common steam-chamber into which the other ends of the series of chambers open, a relief-passage and, located in said series of chambers, a series of valves which control communication between said chambers and the relief-passage, said chambers and relief and steam passages being formed in one casting, and arranged in an annular row, centrally-disposed means for actuating the casting to its support, and a steam-supply, pipe connections between said steam-supply and steam-chamber, and a three-way cock, one branch being connected to the steam-supply, one to the steam-chamber and the third to waste, as set forth.

7. A relief-valve arrangement for locomotive and other engines, comprising a series of chambers, a passage leading from one end of each chamber to a space to be relieved, a common steam-chamber into which the other ends of the series of chambers open, a relief-passage, located in said series of chambers, a series of valves which control communication between said chambers and the relief-passage, said chambers and relief and steam passages being formed in one casting, and arranged in an annular row, centrally-disposed means for actuating the casting to its support, a series of openings in said casting, one opposite each chamber and each closed by a cover-plate, and a steam-supply, pipe connections between said steam-supply and steam-chamber, and a three-way cock one branch being connected to the steam-supply, one to the steam-chamber and the third to waste, as set forth.

700,846. NAIL-PULLER. IRVING W. STUBBS, Oyster Bay, New York. Filed July 21, 1901. Serial No. 78,104. (No model.)

Claim.—1. An improved nail-puller, comprising a body member adapted to rest upon the work and embodying a fixed jaw, and a movable jaw carried by said body member in opposition to said fixed jaw and provided with a projecting portion adapted to be engaged by a hammer or other implement whereby the latter may be operatively borne upon said body member to grip the jaws in engagement with the nail and to exert the activity to extract the nail.

2. An improved nail-puller, comprising a body member adapted to rest upon the work and embodying as one end a fixed jaw, and a pivoted jaw carried by said body member in opposition to said fixed jaw and provided with a projecting portion which extends above the body member and is adapted to be engaged by a hammer or other implement whereby the latter may be operatively borne upon said body member to grip the jaws in engagement with the nail and to exert the activity to extract the nail.

3. The combination, with a nail-puller, comprising a body member adapted to rest upon the work and embodying a fixed jaw, and a movable jaw carried by said body member in opposition to said fixed jaw and provided with a projecting portion which extends above the body member; of a draw-hammer the bifurcation of the claw of which are caused to straddle said projecting portion of said movable jaw whereby the head of the hammer may be operatively borne upon said body member to grip the jaws in engagement with the nail and to exert the activity to extract the nail.

4. An improved nail-puller, comprising an elongated body member adapted to rest upon the work and embodying at its respective ends a fixed jaw and a curved flat, said body member being chambered vertically adjacent to said fixed jaw to form cheeks, and a movable jaw pivoted between said cheeks and arranged in opposition to said fixed jaw, said movable jaw being provided with a projecting portion which extends above the body member and is adapted to be engaged by a hammer or other implement whereby the latter may be operatively borne upon said body member to grip the jaws in engagement with the nail and to exert the activity to extract the nail.

700,847. REGULATOR FOR ALTERNATING-CURRENT CIRCUITS. CHARLES F. SUMNER, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Aug. 16, 1897. Serial No. 68,922. (No model.)

Claim.—1. In a regulator for alternating-current circuits, the combination of a core structure comprising relatively movable members, with compensator-coils so arranged thereon that by adjustment of the said core structure a magnetic circuit can be closed through both portions of the respective compensator-coils, or through a single portion only.

2. In a regulator for polyphase circuits, the combination of a core structure composed of external and internal parts, angularly adjustable with reference to each other around an axis, compensator-coils connected at intermediate points to the regulated circuit, and arranged upon the core structure in such a manner that a magnetic circuit can be closed through both parts of the respective compensator-coils, or through a single part only, by adjustment of the core structure, as set forth.

3. The combination of a stationary core part, an adjustable core part, and a compensator-winding, the two parts of which occupy different angular positions on two of said core parts, as set forth.

4. In a regulator for alternating-current circuits, the combination of a core structure comprising two relatively adjustable members, one of said members provided with two sets of polar projections, and the other with a single set, and compensator-coils having portions embracing the polar projections of one member; the polar projections of the other member being unrounded.

5. In a regulator for alternating-current circuits, two relatively adjustable members, one of said members having two sets of polar projections and the other having only a single set, in combination with compensator-coils, each comprising a series portion and a shunt portion, the series portions of said coils embracing the polar projections of one set, the shunt portions embracing the polar projections of a second set, and the third set being unrounded.

6. The combination of an alternating-current circuit, a branch circuit, a compensator-winding through which the second circuit is connected with the first circuit, and means for adjusting the parts making up the core of the regulator so that the series and shunt portions of the compensator-winding may be placed in inductive relation to one another, and gradually withdrawn from inductive relation by opening the magnetic circuit of the series portion of the compensator-winding and simultaneously closing the magnetic circuit of the shunt portion, as set forth.

7. The combination in a regulator for polyphase circuits, of a core structure composed of external and internal parts adjustable with reference to each other around an axis, a compensator-coil for each phase, part of which is in series and part in shunt with the load on the corresponding branch of the regulated circuit, and means for adjusting the core structure so as to put the series and shunt branches of the compensator-coils in inductive relation with one another for lower voltage in the regulated circuit, and at another time gradually withdraw them from inductive relation until at maximum voltage the shunt branches of the compensator-coils stand in a closed magnetic circuit, and are practically idle, while the series branches of the compensator-coils stand in a practically open magnetic circuit, as set forth.

8. In a regulator for alternating-current polyphase circuits, the combination of a core structure, compensator-coils having series and shunt branches with relation to a regulated circuit, and means for varying the magnetic circuit through the series and shunt branches of the compensator-coils such that (a) said series and shunt branches may be in inductive relation in a closed magnetic circuit; (b) the series branch may have its magnetic circuit closed and that of the shunt open; (c) the shunt branch may have its magnetic circuit closed and that of the series open; as set forth.

9. In a regulator for polyphase circuits, the combination of a core or core, a compensator-coil for each phase of the circuit having a portion in series and another portion in shunt with the regulated circuit, and means for varying the mutual inductance between the shunt and series portions of the coils, and also their self-inductance in order to change the distribution of voltage between different portions of said coils, as set forth.

10. The combination with an alternating-current source, of a regulator character consisting of a compensator-coil connected across the main circuit and having a series and shunt portion between which the motor

connection is made, a magnetic core structure for the compensator-coil, and means for regulating the voltage at the motor-terminals by varying the mutual induction and self-induction of the series and shunt branches of the compensator-winding.

700,848. VARIABLE-SPEED GOVERNOR. WILLIAM J. HULL, Toronto, Canada. Filed Apr. 22, 1926. Renewed Apr. 18, 1928. Serial No. 108,322. (No model.)

Claim.—1. A variable-speed governor comprising a crank attached to a revolving support held in suitable bearings, a spring-controlled arm pivoted to said crank, a leg placed in the path of movement of said arm so as to operate said spring-controlled arm at each revolution of said revolving support, as described, a guiding-plate placed in the path of movement of said arm so as to guide the movement of said arm above or below said plate as the speed of the support rises or falls, and means in the path of said arm, being operated by same, for regulating the speed of said revolving support, as set forth and for the purpose specified.

2. A variable-speed governor comprising a crank attached to a revolving support held in suitable bearings, a spring-controlled arm pivoted on said crank, a leg placed in the path of movement of said arm so as to operate said spring-controlled arm at each revolution of said revolving support, as described, a guiding-plate placed in the path of movement of said arm so as to guide the movement of said arm above or below said plate as the speed of the revolving support rises or falls, means for varying the position of said guiding-plate relative to the path of movement of said arm for increasing or diminishing the speed of said revolving support, and means in the path of said arm, being operated by same, for regulating the speed of said revolving support, as set forth and for the purpose specified.

3. A variable-speed governor comprising a crank attached to a revolving support held in suitable bearings, a spring-controlled arm pivoted on said crank, a leg placed in the path of movement of said arm so as to operate said spring-controlled arm at each revolution of said support, as described, a guiding-plate placed in the path of movement of said arm so as to guide the movement of said arm above or below said plate as the speed of the said support rises or falls, automatic means for varying the position of said guiding-plate relative to the path of movement of said arm for increasing or diminishing the speed of said revolving support, and means in the path of said arm, being operated by same, for regulating the speed of the said revolving support, as set forth and for the purpose specified.

4. A variable-speed governor comprising a crank attached to a revolving support held in suitable bearings, a spring-controlled arm pivoted on said crank, a leg placed in the path of movement of said arm so as to operate said arm at each revolution of said revolving support, and a spring-controlled guiding-plate in the path of movement of said spring-controlled arm incapable of offering frictional resistance to the motion of said arm in case of contact between said arm and said spring-controlled plate, as set forth and for the purpose specified.

700,849. HASEL. HENRY H. GREGG, Chicago, Ill. Filed Sept. 26, 1901. Serial No. 78,900. (No model.)

Claim.—1. An oscill comprising a front plate, a back plate hinged to said front plate and foldable against same, and a bifurcated brace extend-

ing said back plate, hinged to said front plate at each side of said back plate and on an axis transverse to the axis of said back plate, said brace being foldable against the front plate, and adapted when turned on its axis to a position away from said front plate to hold said back plate in a plane disposed transversely to the plane of the front plate.
